Late Miocene hominids from the Middle Awash, Ethiopia

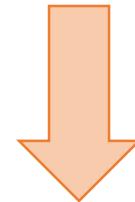

Yohannes Haile-Selassie

Department of Integrative Biology and Laboratory for Human Evolutionary Studies, Museum of Vertebrate Zoology, 3060 VLSB, University of California, Berkeley, California 94720, USA

Molecular studies suggest that the lineages leading to humans and chimpanzees diverged approximately 6.5–5.5 million years (Myr) ago, in the Late Miocene^{1–3}. Hominid fossils from this interval, however, are fragmentary and of uncertain phylogenetic status, age, or both^{4–6}. Here I report new hominid specimens from the Middle Awash area of Ethiopia that date to 5.2–5.8 Myr and are associated with a wooded palaeoenvironment⁷. These Late Miocene fossils are assigned to the hominid genus *Ardipithecus* and represent the earliest definitive evidence of the hominid clade. Derived dental characters are shared exclusively with all younger hominids. This indicates that the fossils probably represent a hominid taxon that postdated the divergence of lineages leading to modern chimpanzees and humans. However, the persistence of primitive dental and postcranial characters in these new fossils indicates that *Ardipithecus* was phylogenetically close to the common ancestor of chimpanzees and humans. These new findings raise additional questions about the claimed hominid status of *Orrorin tugenensis*⁸, recently described from Kenya and dated to ~6 Myr⁹.

(Nature 412, 2001)

Ardipithecus ramidus kadabba

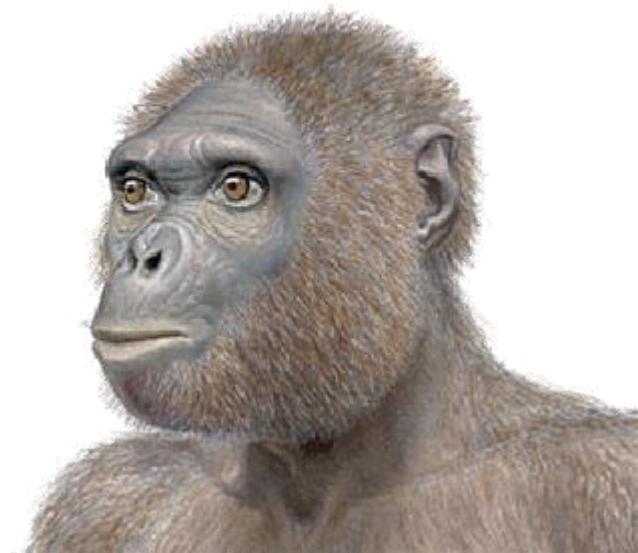

Ardipithecus kadabba

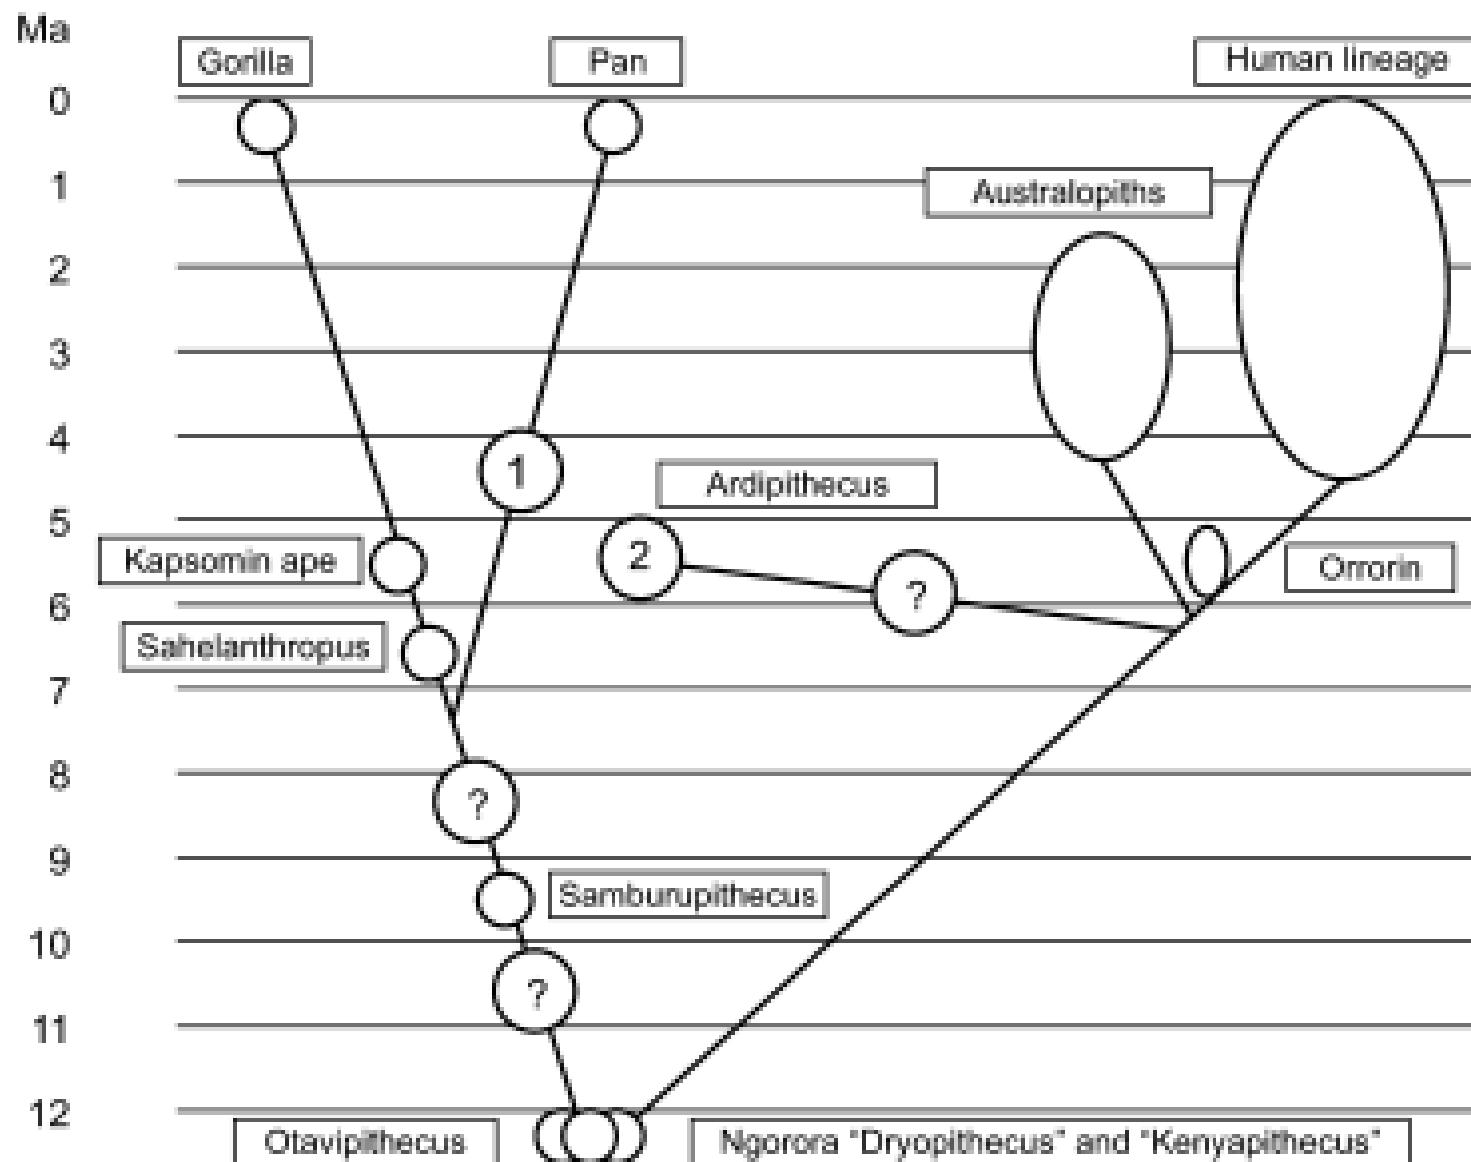

Tendenza dei canini ad essere incisiformi

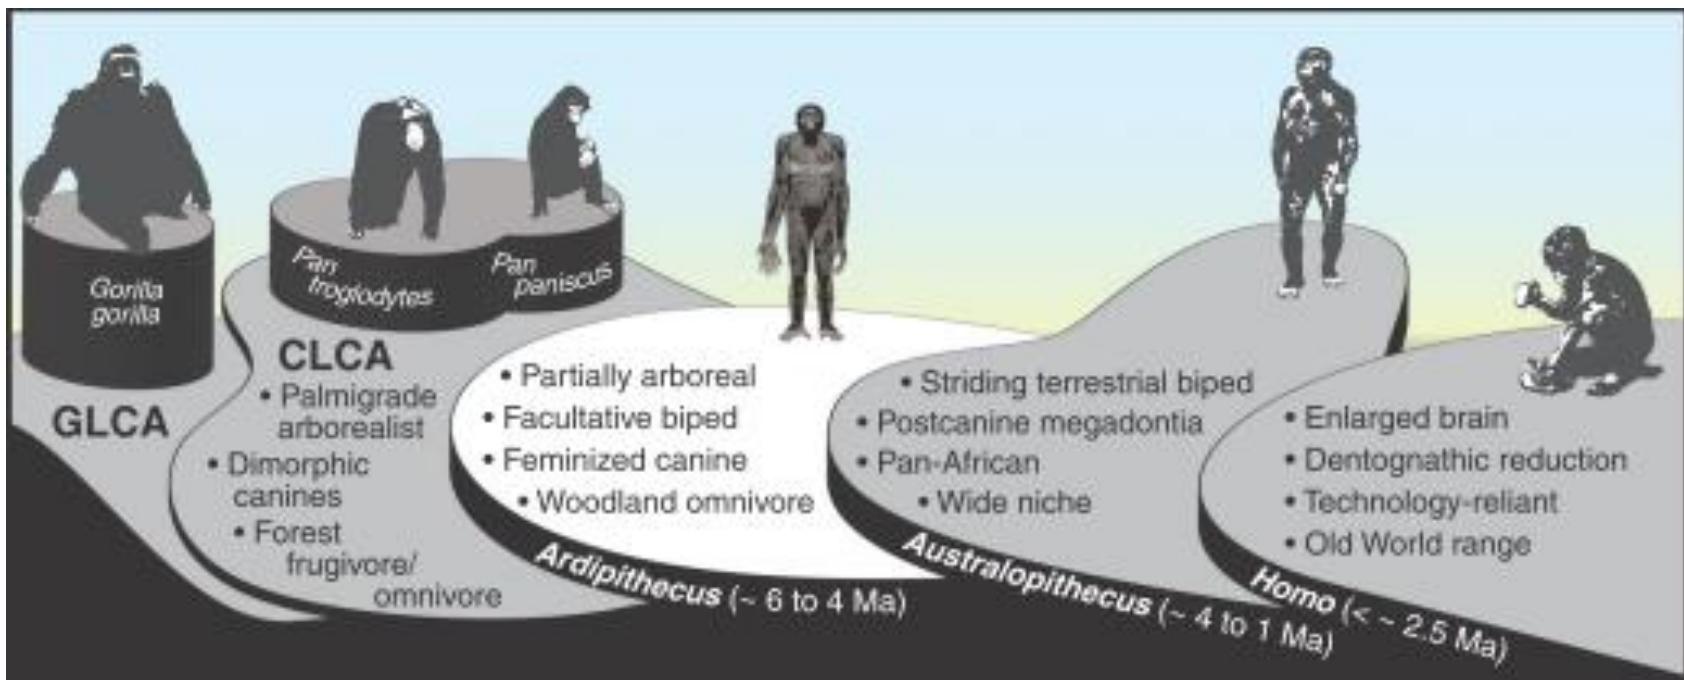

Elementi post-craniali simili a quelli delle grandi scimmie : adattamento alla vita arboricola

Differenza tra *Ar. kadabba* e *Ar. ramidus* nelle radici dei denti

Proposed relationships between early hominids and late apes

Evolution of hominids and African apes since the gorilla/chimp+human (GLCA) and chimp/human (CLCA) last common ancestors. Pedestals on the left show separate lineages leading to the extant apes (gorilla, and chimp and bonobo); text indicates key differences among adaptive plateaus occupied by the three hominid genera.

Ardipithecus ramidus and the Paleobiology of Early Hominids

Tim D. White,^{1*} Berhane Asfaw,² Yonas Beyene,³ Yohannes Haile-Selassie,⁴ C. Owen Lovejoy,⁵ Gen Suwa,⁶ Giday WoldeGabriel⁷

Fig. 1. Geography and stratigraphy of the Aramis region. Two dated volcanic horizons constrain the main *Ardipithecus*-bearing stratigraphic interval in the Aramis region. The top frame shows these tephra in situ near the eastern end of the 9-km outcrop. The dark stripe in the background is the riverine forest of the modern Awash River running from right to left, south to north, through the Middle Awash study area of the Afar Rift. The lower frames are contemporaneous helicopter views over ARA-VP-1 (Yonas Molar Site) to show the geographic position of the top photo and to depict the extensive outcrop of the upper tuff horizon (dotted lines show the DABT) across the local landscape. Vehicles are in the same position to provide orientation. Sediments outcropping immediately below this 4.4-million-year-old horizon yielded the floral, faunal, and isotopic contexts for *Ar. ramidus*. The frame to the left shows the slight eastward dip of the Sagantole Formation toward the modern Awash River. The contiguous frame to the right is a view up the modern upper Aramis catchment. The ARA-VP-6 locality where the partial *Ardipithecus* skeleton was excavated is near its top right corner (Fig. 2).

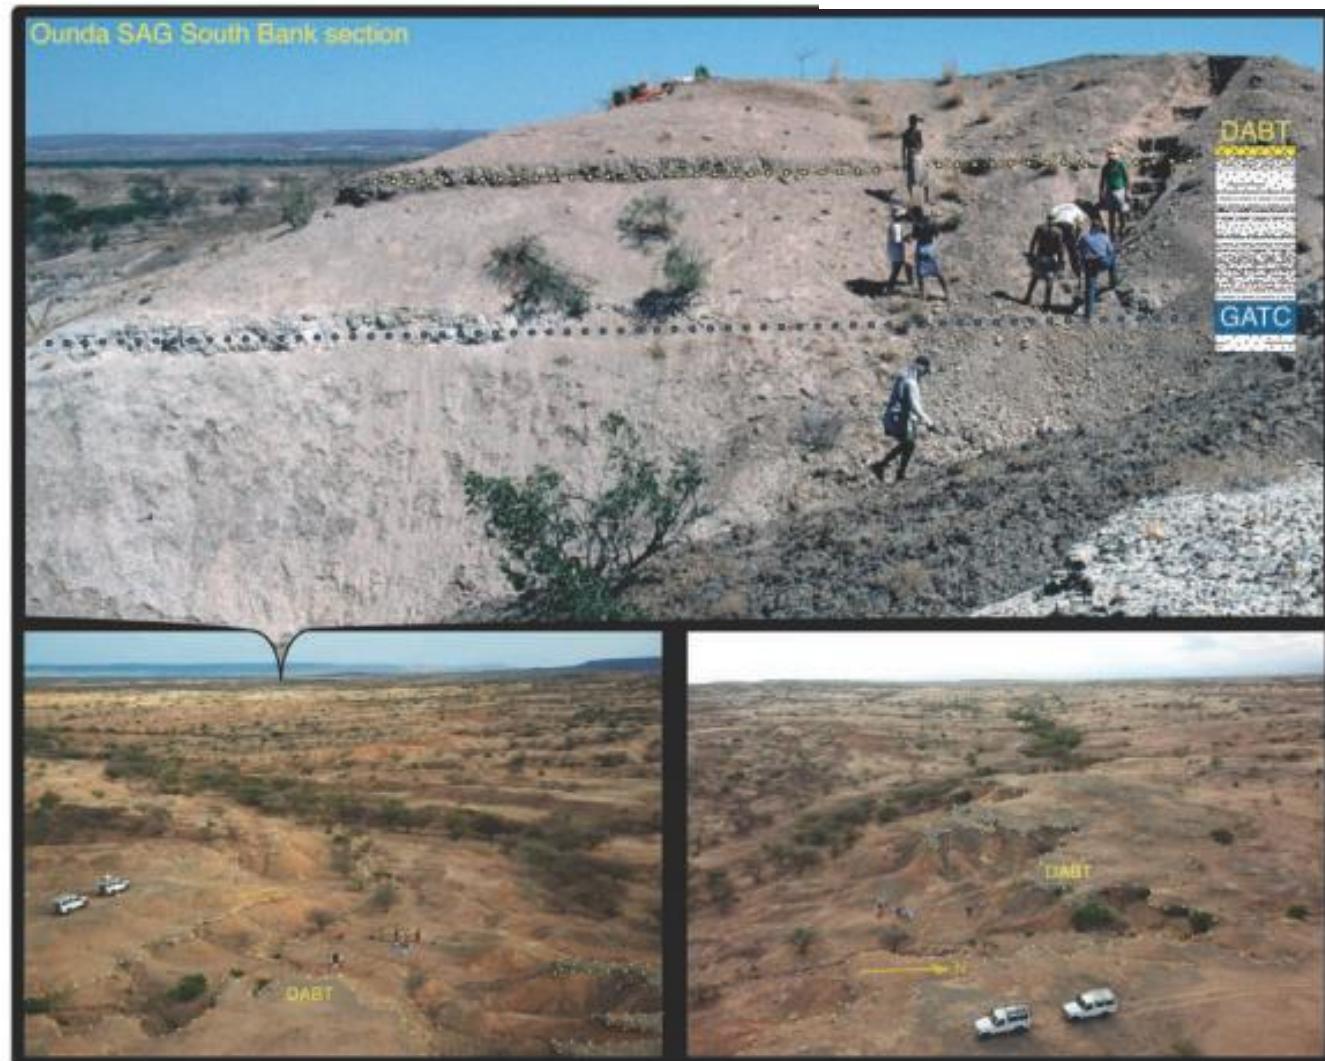

Figure 1 illustrates the geological context of the *Ardipithecus ramidus* find. The top photograph shows the Ounda SAG South Bank section, a 9-km long outcrop where two dated volcanic horizons (DABT and GATC) constrain the main *Ardipithecus*-bearing stratigraphic interval. The lower photographs are contemporaneous helicopter views over the ARA-VP-1 site, showing the extensive outcrop of the upper tuff horizon (DABT) across the local landscape. The ARA-VP-6 locality, where the partial *Ardipithecus* skeleton was excavated, is indicated in the right-hand aerial view. The figure also shows the slight eastward dip of the Sagantole Formation toward the modern Awash River.

Ardipithecus ramidus and the Paleobiology of Early Hominids

Tim D. White,^{1*} Berhane Asfaw,² Yonas Beyene,³ Yohannes Haile-Selassie,⁴ C. Owen Lovejoy,⁵ Gen Suwa,⁶ Giday WoldeGabriel⁷

Età: 4.4 Ma

- 110 resti ritrovati
- 50 kg , 120 cm di altezza
- Piccole differenze nella taglia corporea tra maschio e femmina

Little body size difference between males and females

- Capacità cranica / *Brain size* = chimpanzees
- Faccia piccola e canini/premolari ridotti (riduzione delle competizioni sociali)

Small face and reduced canine/premolar complex (minimal social aggression)

- Nessuna sospensione, o knuckle-walking ma una bipedia più primitiva che i Australopitecini

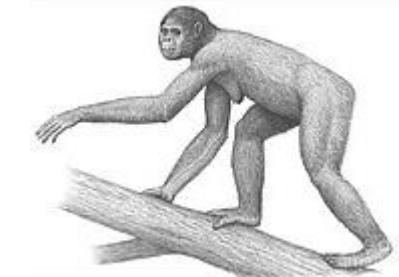

No suspension, vertical climbing or knuckle-walking but more primitive bipedalism than Australopithecus

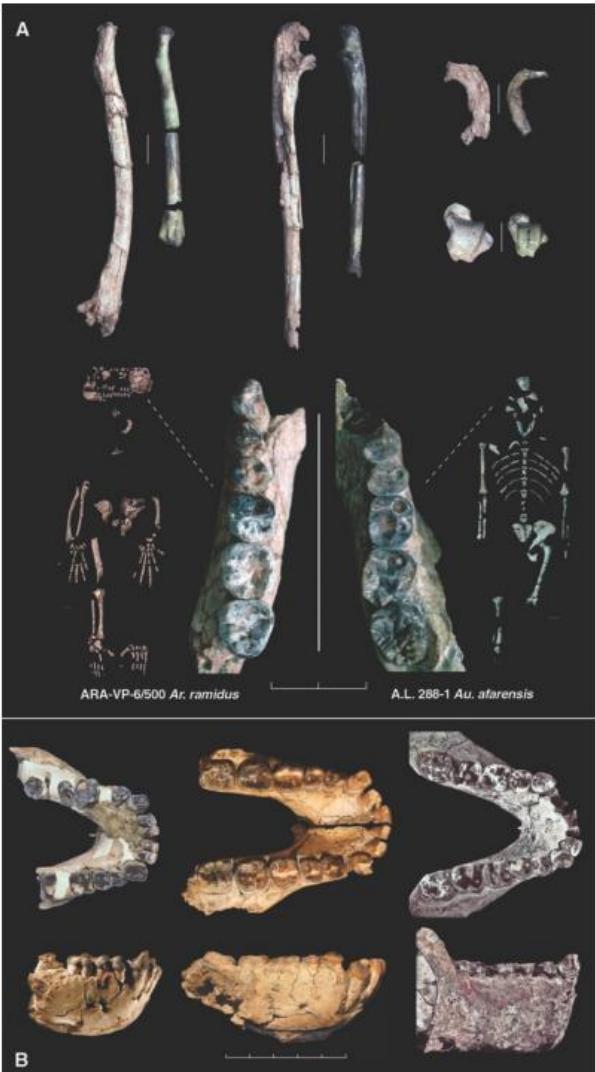

- Riduzione dello spessore dello smalto in confronto a *Australopithecus*

Reduced thickness of the enamel compared to Australopithecus

Ar. *Ramidus* indica che gli ultimi antenati comuni tra i umani e le scimmie africane non erano «chimpanzee-like» e che gli ominidi e le scimmie africane estinti sono fortemente specializzati, ma attraverso un cammino evolutivo molto diverso.

Ar. *ramidus thus indicates that the last common ancestors of human and African apes were not chimpanzee-like and that both hominids and extant African apes are each highly specialized, but through very different evolutionary pathways.*

I scheletri dimostrano delle dimensioni postcraniali importanti relativamente alle dimensione dentarie

Skeletal individuals illustrate larger postcranial dimensions for the Ardipithecus individual relative to dental size.

Confronti tra dimensioni dentarie post canini rivelano la megadontia dei *Australopithecini*.

Comparison of the postcanine dentitions reveals the megadontia of the Australopithecus individual

Fig. 3. The ARA-VP-6/500 skeleton. This is a composite photograph to show the approximate placement of elements recovered. Some pieces found separately in the excavation are rejoined here. Intermediate and terminal phalanges are only provisionally allocated to position and side.

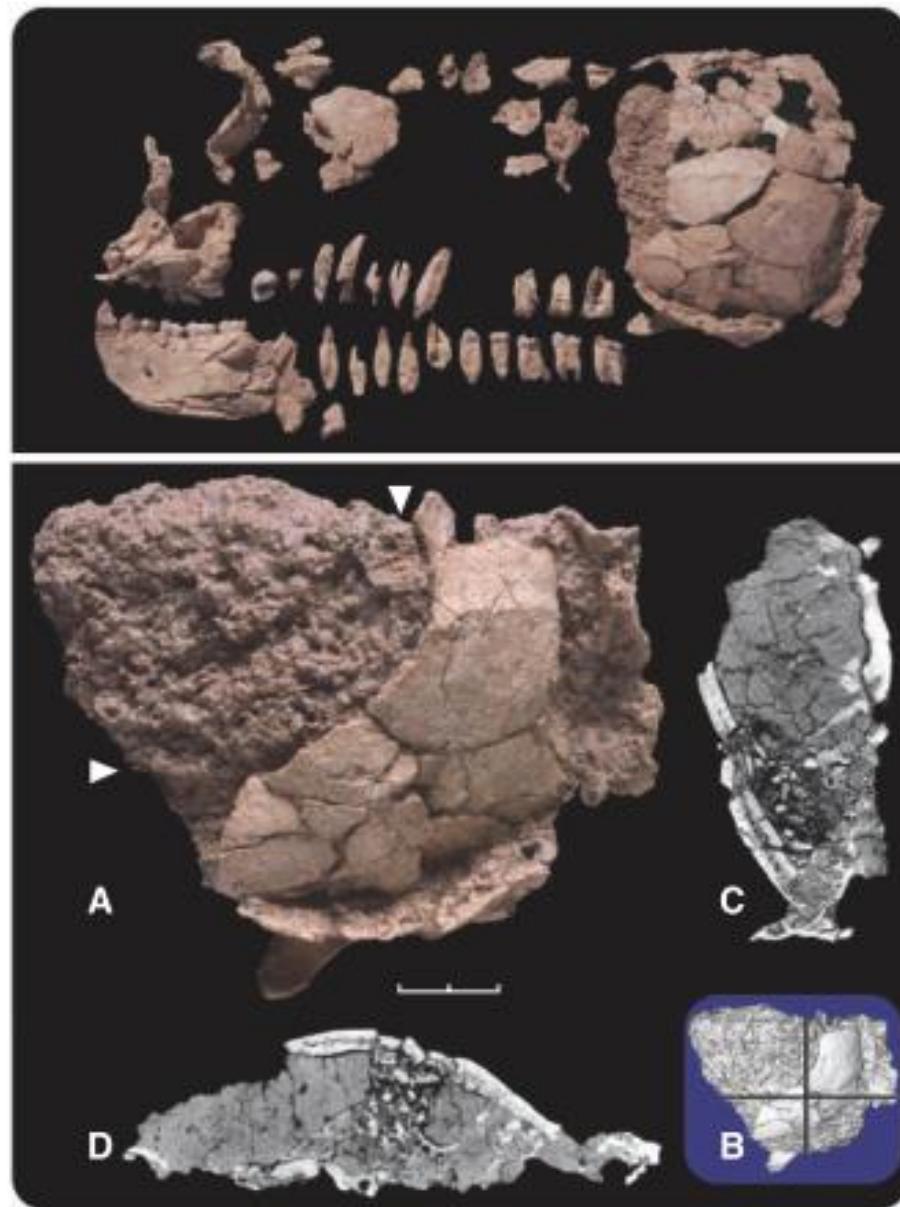

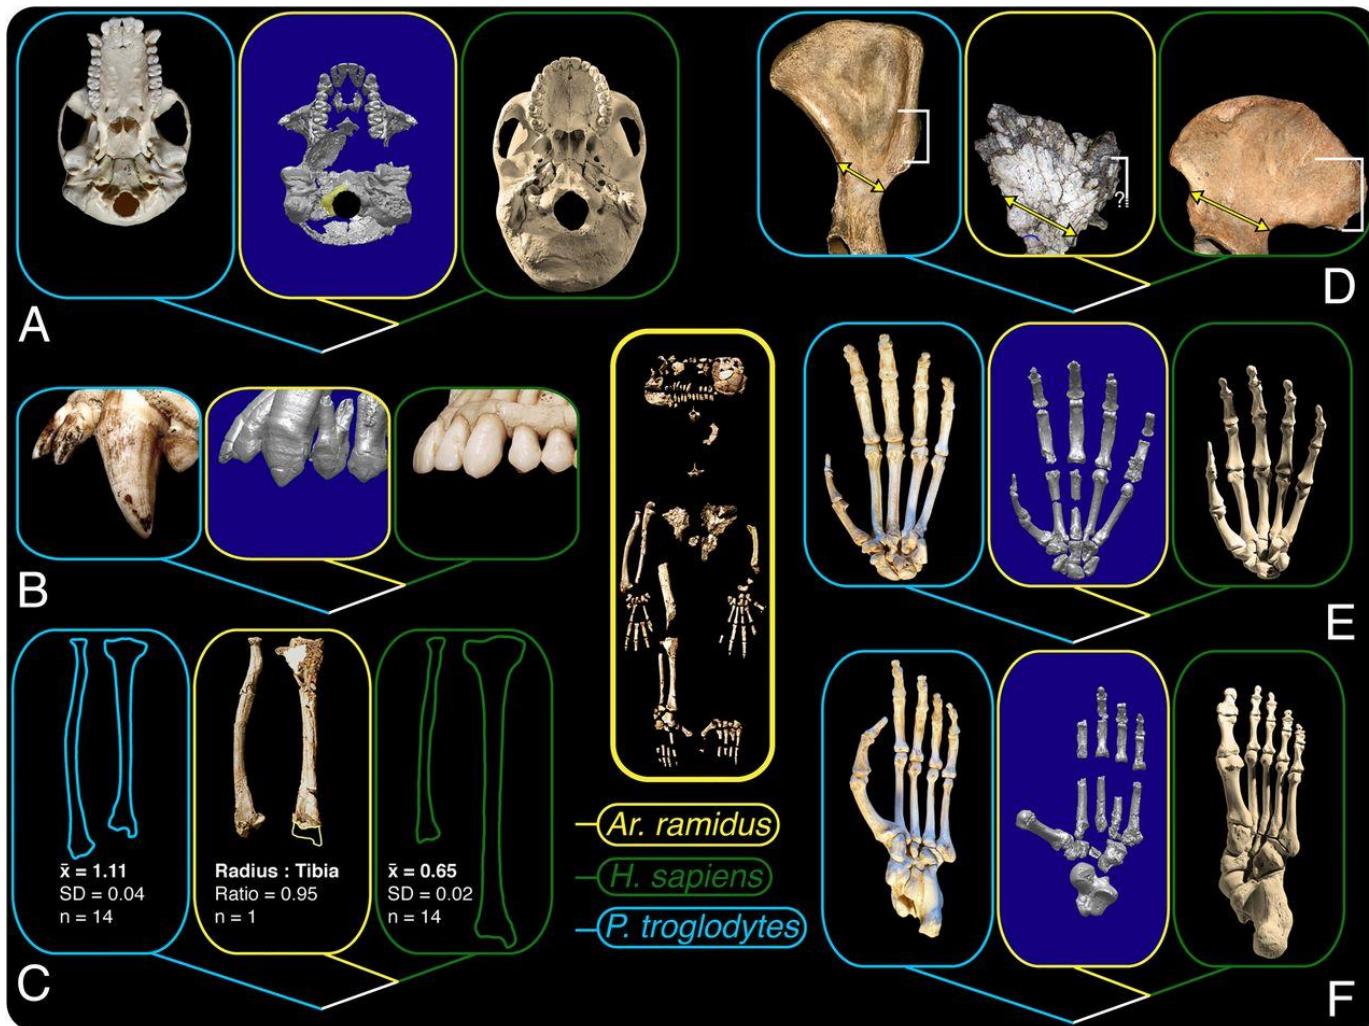

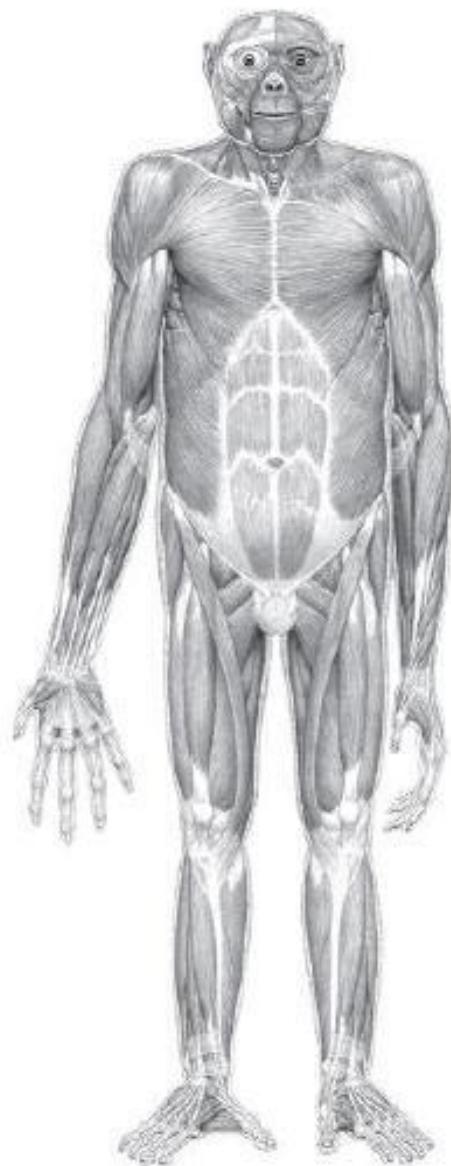

Fig. 1. The fragmented skull of *ARA-VP-6/500*. (Upper panel) Identifiable pieces of the skull after limited refitting for digital and physical molding. (Lower panel) (A) *ARA-VP-6/500-032*, (B) micro-CT rendered image of the same, with cross-sectional locations of (C) and (D) indicated. Arrowheads in (A) denote the positions of (C) and (D).

Evolution in different directions.

1 ipotesi: tutte le evidenze conosciute rappresentano un'unica linea evolutiva

2 ipotesi; raffigura la stessa evidenza di una transizione diretta tra *Ardipithecus* e *Australopithecus* (speciazione) accaduta tra 4,5 e 4,2 Ma in un gruppo di popolazione regionale (o locale) che potrebbe avere incluso I rift dell'Afar e Turkana.

3 ipotesi: consente una speciazione allopatica (cladogenesi attraverso una microevoluzione accumulata in una popolazione periferica isolata che è diventata separata al livello riproduttivo.

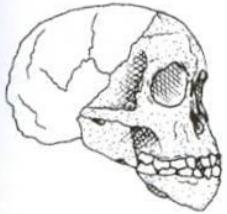

Hypothesis 1 interprets all known evidence to represent a species lineage evolving phyletically across its entire range.

Hypothesis 2 depicts the same evidence in an *Ardipithecus*-to-*Australopithecus* transition (speciation) occurring between ~4.5 and ~4.2 Ma in a regional (or local) group of populations that might have included either or both the Afar and Turkana rifts.

Hypothesis 3 accommodates the same evidence to an alternative, much earlier peripheral allopatric speciation model (cladogenesis through microevolution accumulated in a peripheral isolate population, becoming reproductively separated).

Holotype : Crâne KNM-WT 40000 (Lomekwi, Ouest-Turkana, Kenya)

Australopithecus

Caratteristiche condivise dalle Australopitecine

1. Dimensione del cervello ± scimpanze (ca. 375-550 cm³)
2. Parte mesio-facciale vertical e corta inferio-superiormente con una regione zigomaticomassellare massiccia e un forte prognatismo subnasale
3. Basicranio corto con un foramen magnum posizionato anteriormente
4. Canini ridotti e non affilati
5. Premolari e molari grandi (in rapporto alla taglia del corpo) con smalto spesso
6. Corpo mandibolare spesso trasversalmente e rami alti

Australopithecus

Shared australopith characteristics

1. An approximately ape-size brain (range ca. 375-550 cm³)
2. Inferosuperiorly short, vertical mid-face with massive zygomaticomaxillary region and strong subnasal prognathism
3. Short basicranium with anteriorly positioned foramen magnum
4. Absolutely small, nonhoning canines
5. Large (in relation to body size) premolars and molars capped by variably thick enamel
6. Transversely thick mandibular bodies and tall ascending rami

Australopithecus anamensis

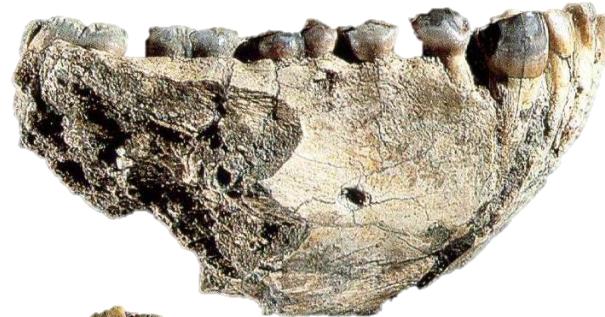

Scoperta: Kanapoi e Allia bay, Kenya
(lago Turkana)

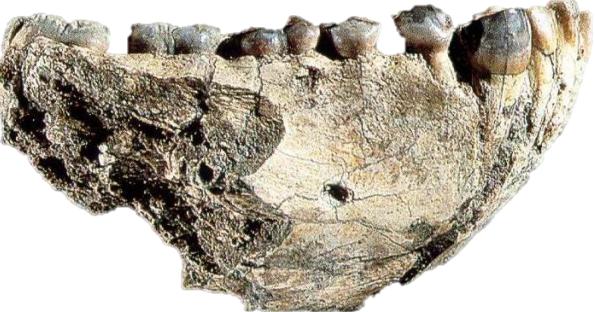

Età: 4,2-4,1 Ma per Kanapoi e 3,9 Ma per Allia Bay

Da Histoire d'ancêtres- Grimaud et al., 2005

- Mandibola stretta con corpo mandibolare quasi parallele
Narrow mandible with almost parallel corpus
- Assenza di diastema
No diastema
- Spessore dello smalto > Ar. ramidus
Enamel thickness > Ar. ramidus

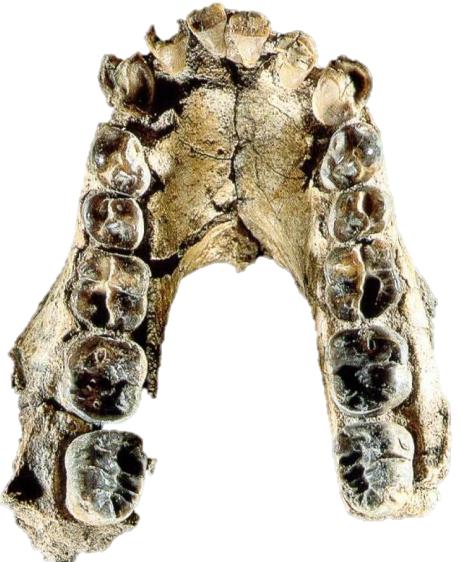

KNM-KP 29 281 4,1 Ma

≠ scimmie esistente e gli ominidi del Mio-Pliocene hominins
(*Ardipithecus* e *Sahelanthropus*)

- Premolari più complessi
- Smalto dei denti giugali più spesso
- Canini meno *ape-like*

≠ australopitecine successive

Morfologia della dentizione, particolarmente nella arcata anteriore

≠ extant African apes and Mio-Pliocene hominins
(*Ardipithecus* and *Sahelanthropus*)

- More complex premolars
- Thicker cheek-tooth enamel
- Canines less apelike

≠ later australopiths

Morphology of the dentition, mostly in the anterior arcade.

KNM-KP 29 281 4,1 Ma

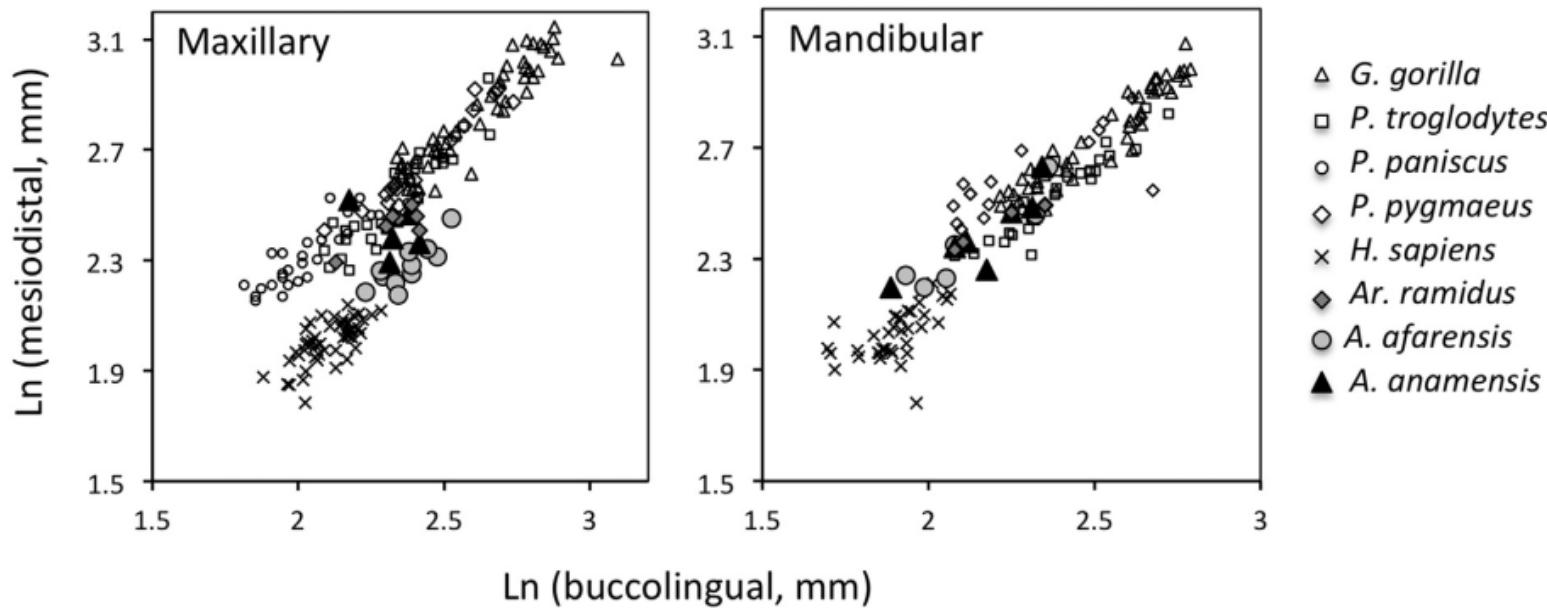

KNM-KP 47953

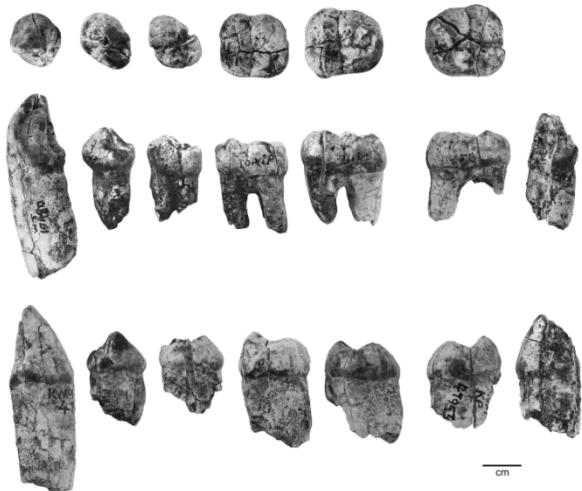

KNM-KP 47956

Canine occlusal shape

Dimensioni della corona dei canini (Ward, JHE 2013)

La forma dei canini di *Au. anamensis* è più simile ai *Ar. ramidus* e alle scimmie attuali. Invece, quelli di *Au. afarensis* sono più avvicinabili a quelli dei uomini moderni.

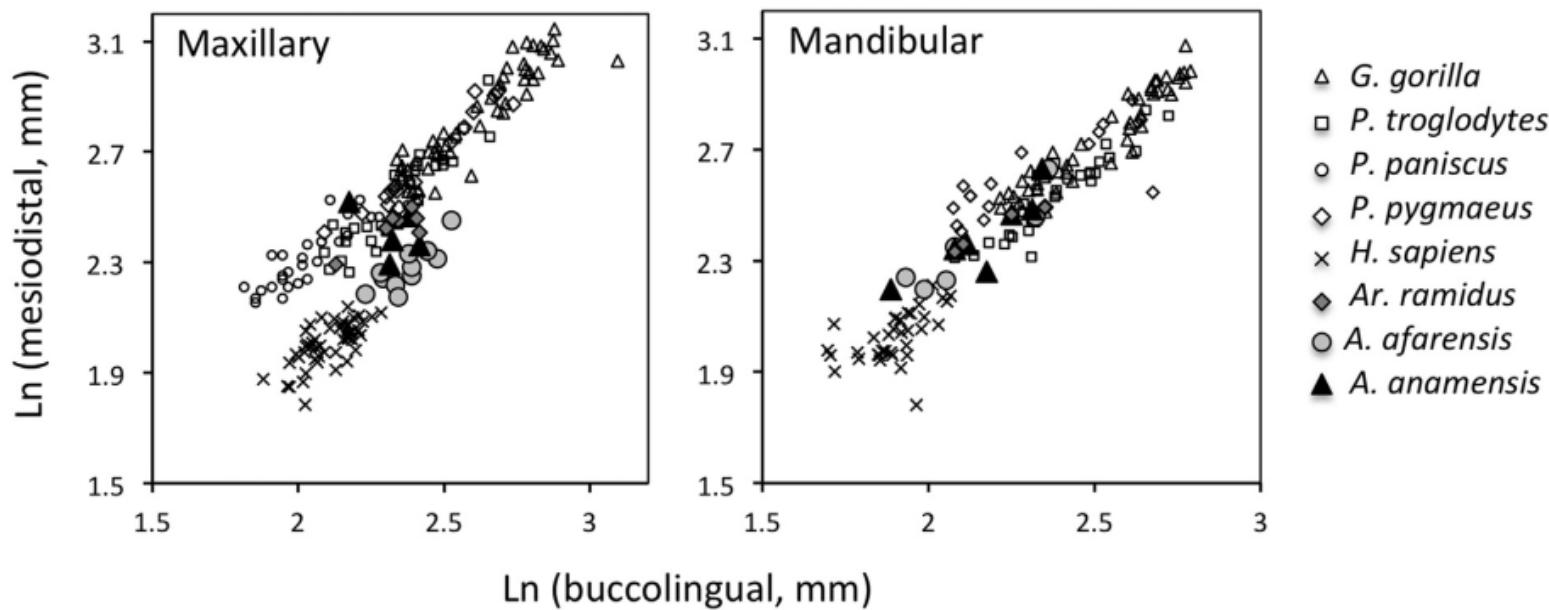

KNM-KP 47953

KNM-KP 47956

Canine occlusal shape

Mandibular canine crown dimensions (Ward, JHE 2013)

Australopithecus anamensis is most like that of Ardipithecus ramidus and extant apes, but those of Australopithecus afarensis are mesiodistally shorter like those of humans.

anamensis VS *afarensis* (Ward, JHE 2013)

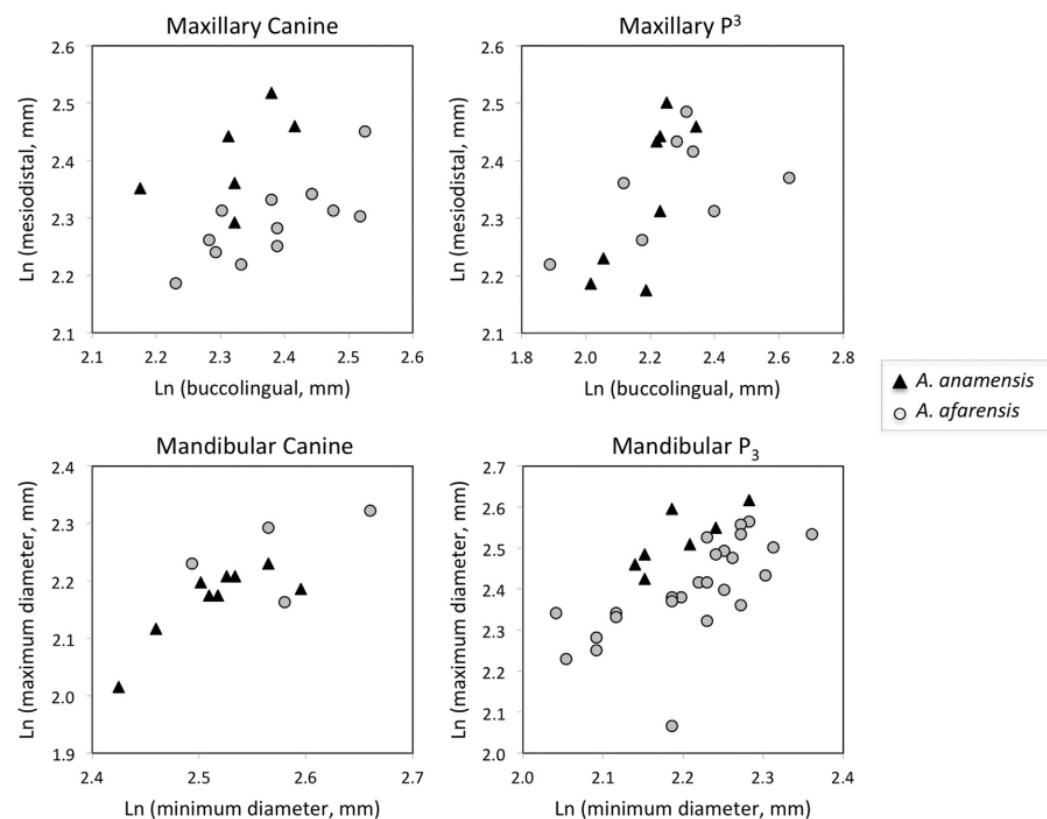

- Morfologia dei canini-premolari distinta, con un affilamento mesiodistale più lungo e delle radici più grande.

Questo dimostra che la perdita della proiezione e del dimorfismo dei canini no è il risultato di un singolo evento ma è stato graduale:

- Diminuzione dell'altezza della corona
- Riduzione della taglia delle radice e della lunghezza mesiodistale dei canini e premolari

Questo suggerisce un cambiamento adattativo della funzione dei canini tra *Au. anamensis* e *Au. afarensis*

Canini e P3 massiliari sono relativamente più lunghi in *Au. anamensis* che in *Au. afarensis*, ma nessuna differenza è notata sui canini e P3 mandibolari.

anamensis VS *afarensis* (Ward, JHE 2013)

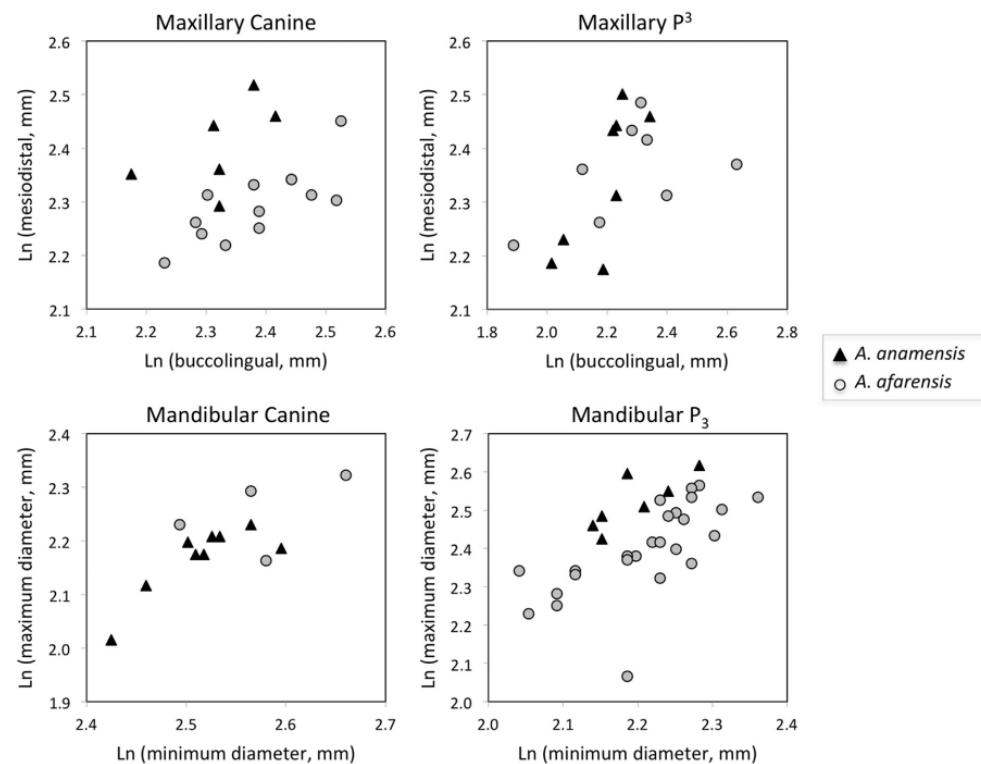

-Distinctive morphology of canine-premolar complex, with mesiodistally longer honing teeth and large canine tooth roots

It is now becoming apparent that the classic hominin characteristic of the loss of projecting canine teeth and canine dimorphism did not result from a single event, but instead occurred in several steps:

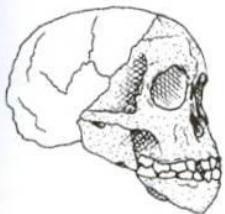

- Diminution of the canine crown heights
- Reduction of the canine and premolar roots size and mesiodistal lengths

This suggests a significant adaptive change in canine function from *Au. anamensis* to *Au. afarensis*

Both the maxillary canine and P 3 are relatively longer in *Australopithecus anamensis* than those of *Au. afarensis*, but no apparent differences are seen in the mandibular canine and P3.

Australopithecus afarensis

Australopithecus afarensis

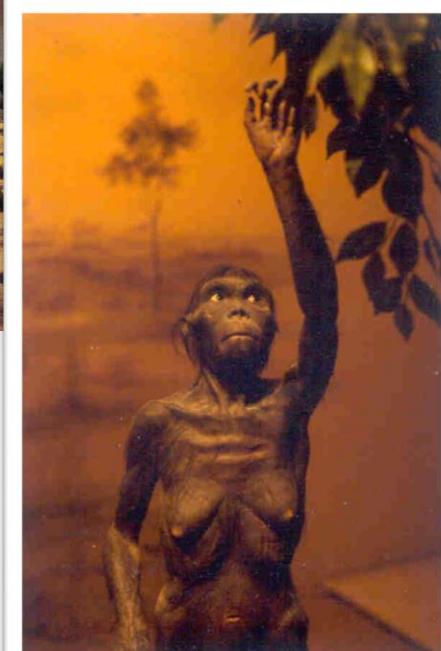

Nom : *Australopithecus afarensis*
 Origine : Afrique de l'Est (Hadar, Laetoli, Maka, Belohdelie, Chémeron, Omo, Koobi Fora)
 Dates : 5 (?) à 3 MA
 Cerveau : 300 à 400 cm³
 Taille : 1,10 m

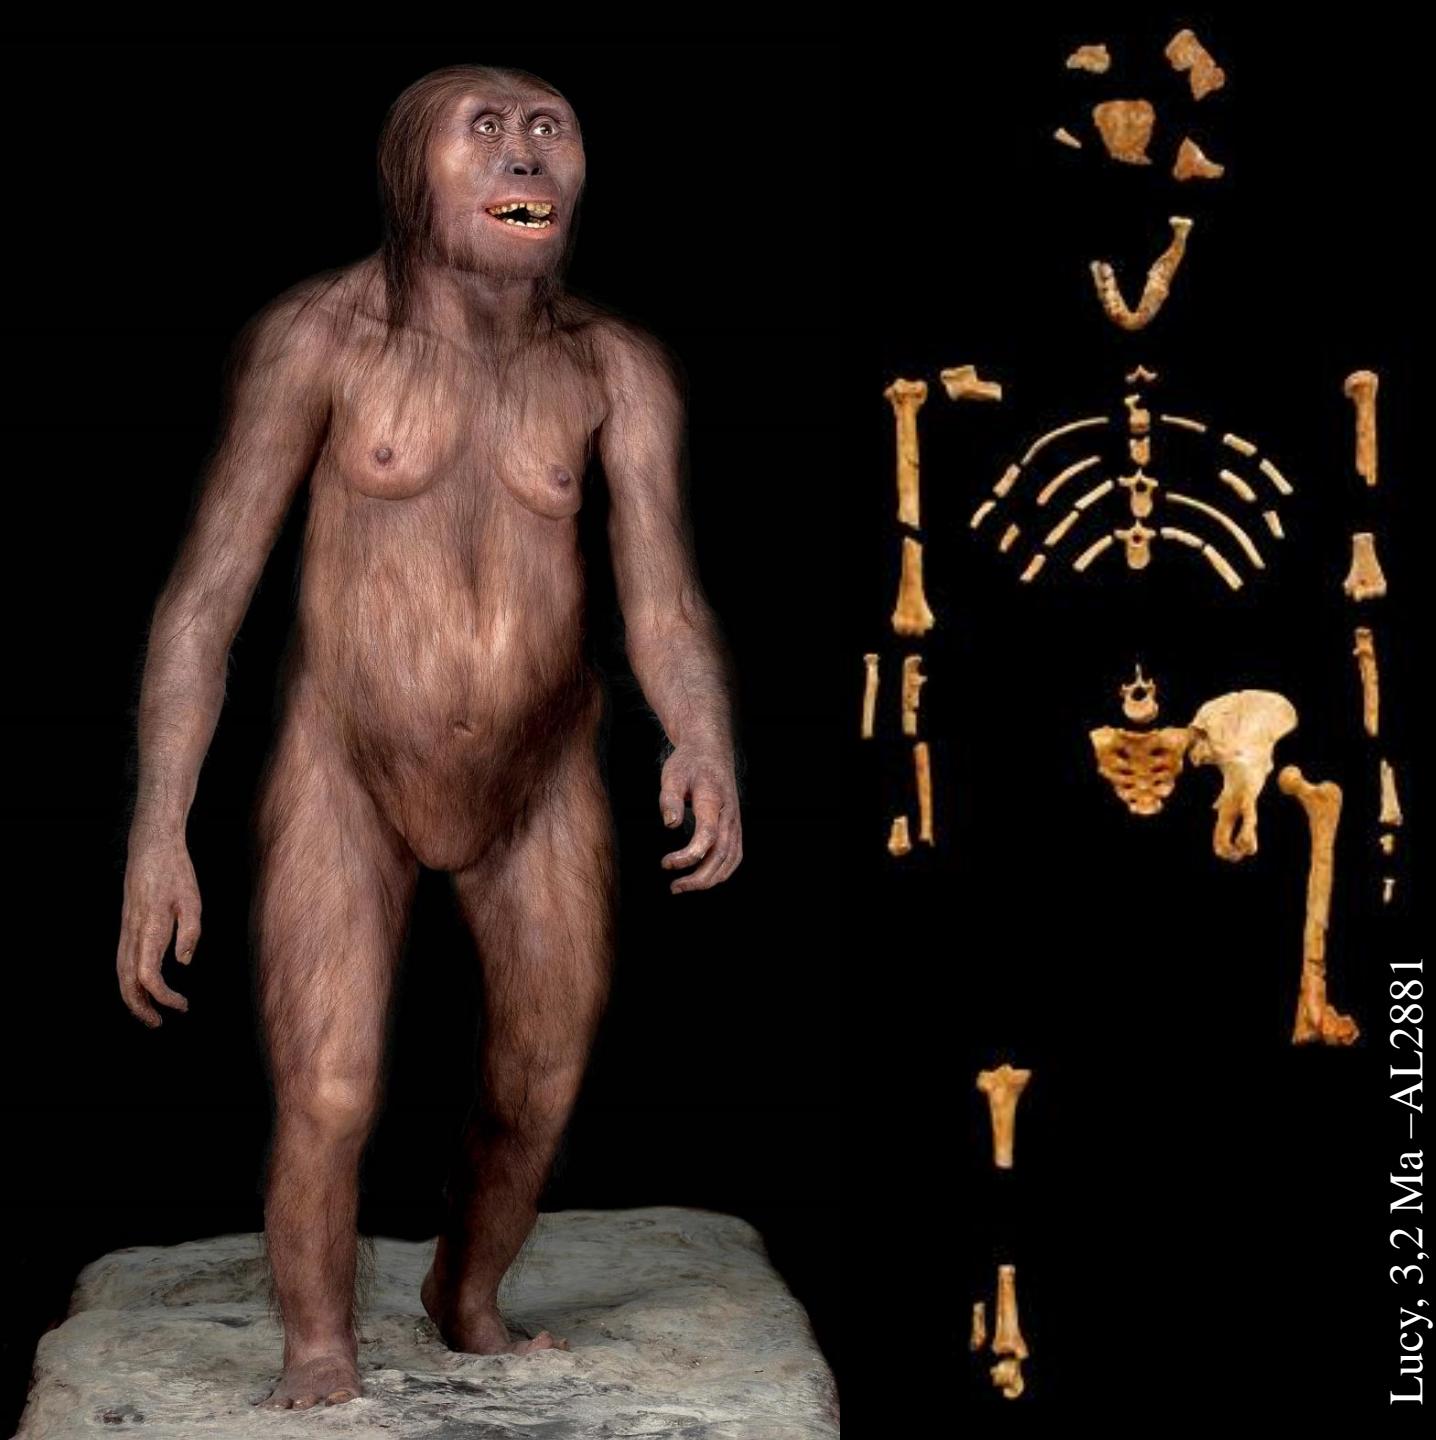

Hadar

AL 444-2 (Hadar, Etiopia 3Ma)

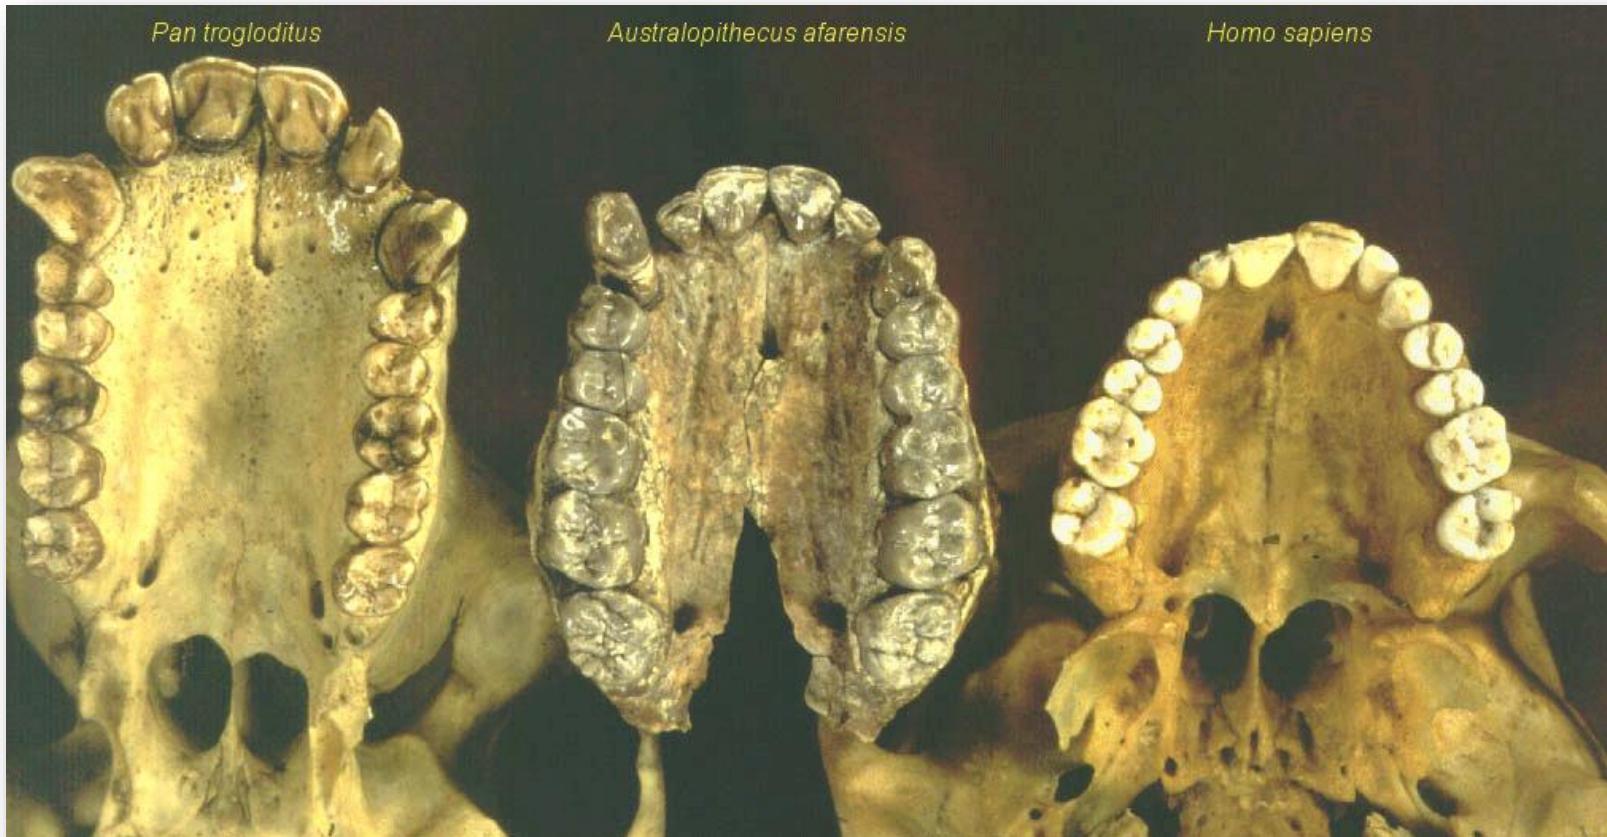

Lucy, 3.2 Ma - AL2881

- Elevato dimorfismo sessuale
- Cranio piccolo
- Scheletro facciale grande e prognato
- Riduzione dei canini e degli incisivi
- Frequente presenza di diastemi
- Bipedismo facoltativo (bambina di DIKИKA Afar) : Cavità glenoidea della scapola è poco profonda inducendo un maggiore movimento dell'omero = vantaggio nella locomozione arboricola

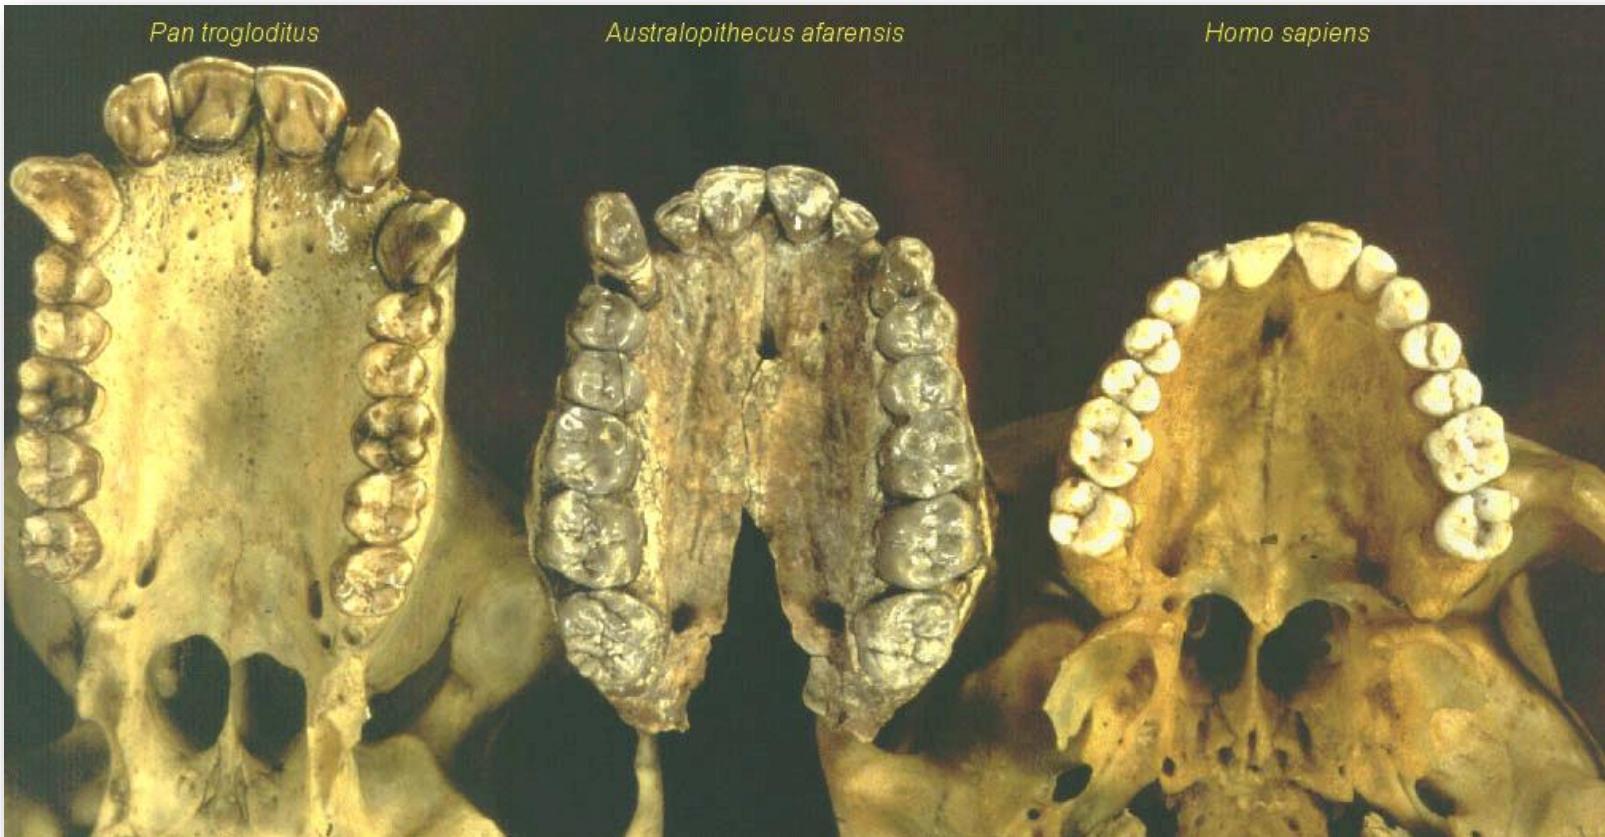

Elevata competizione tra i maschi

- High sexual dimorphism
- Small skull
- Facial skeleton large and prognathous
- Canine and incisors reduction
- Diastema frequently present
- Occasional bipedalism (Dikika Afar child): Narrow scapular glenoid fossa inducing a more important humerus movement = advantage for arboreal locomotion

High competition between male

con *Au. anamensis* (condizione derivata)

- P3 e dm1 più molarizzati
- Palato più largo relativamente alla sua lunghezza
- Apertura nasale definita da margini laterali affilati
- Meato auditivo più largo

con gli altri australopitecine

Anatomia del cranio e dei denti prevalentemente plesiomorfa

Larghezza delle aperture nasale e orbitale strette che contrasta una regione zigomatica massiccia

Per gli individui più grandi: mandibola a U

Canine e premolari in una «transizione evolutiva».

P3 meno molarizzati

AL 444-2 (Hadar, Etiopia 3Ma)

Note: Grande variation nella forma del cranio

- Dimorfismo sessuale (taglia e forma)
- Tendenze anagenetiche nella morfologia craniodentale durante la prima metà (3,5 – 3,0 Ma) della speciazione *anamensis-afarensis*

with *Au. anamensis* (derived condition)

- More molarized P3 and dm₁
- Wider palate at equivalent palate lengths
- Nasal aperture defined by sharp lateral margins
- Larger external auditory meatus

with subsequent australopiths

Predominantly plesiomorphic anatomy of the skull and dentition

Interorbital and nasal aperture breadths are narrow, contrasting with the broad, flat and massive zygomatic region

For larger individual: mandible with U-shape

Canine and premolars captured in evolutionary transition

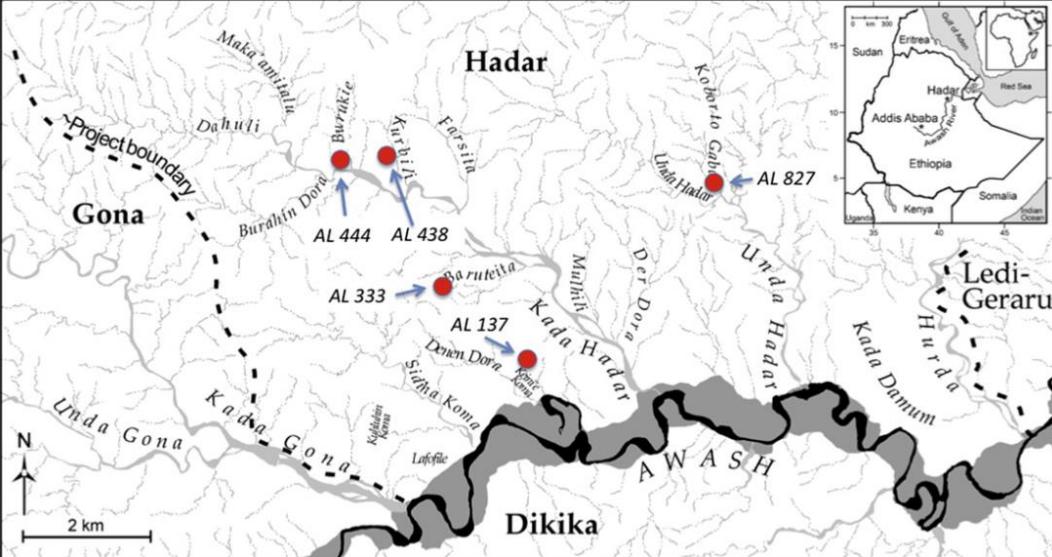

Molarisation of the P3 less advanced

AL 444-2 (Hadar, Etiopia 3Ma)

Note: High level of cranial polymorphism

- Sexual dimorphism in size and shape
- Anagenetic trends in craniodental morphology during the younger half (3,5-3,0 Ma) of the *anamensis-afarensis* species-lineage.

I arti inferiori confermano che *Au. afarensis* iniziava abitualmente ad essere occasionalmente bipede durante la loro ontogenesi.

The lower limb remains confirm that Au. afarensis individuals habitually engaged in upright terrestrial bipedality throughout their ontogeny

AL 333-141

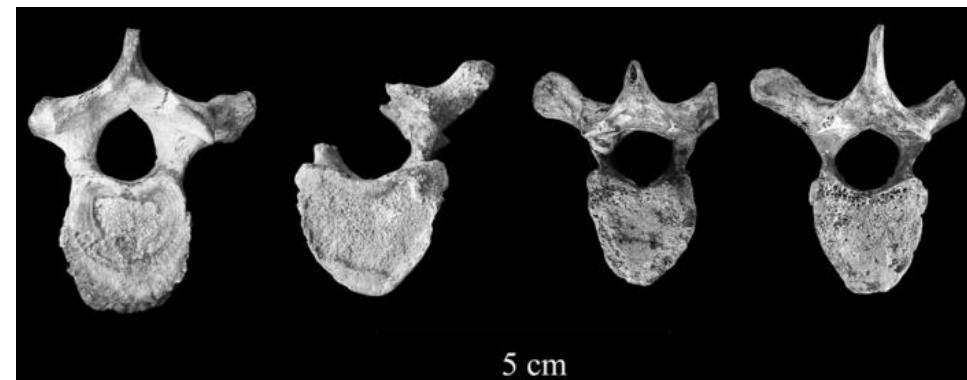

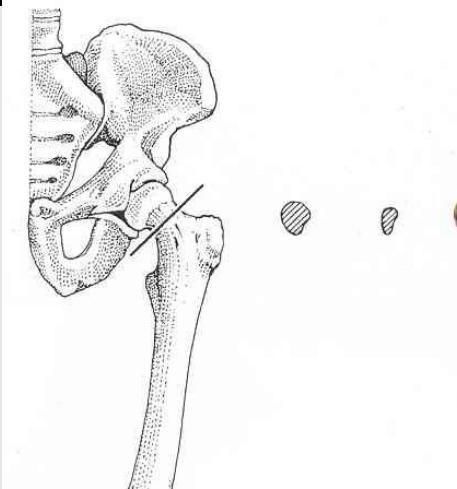

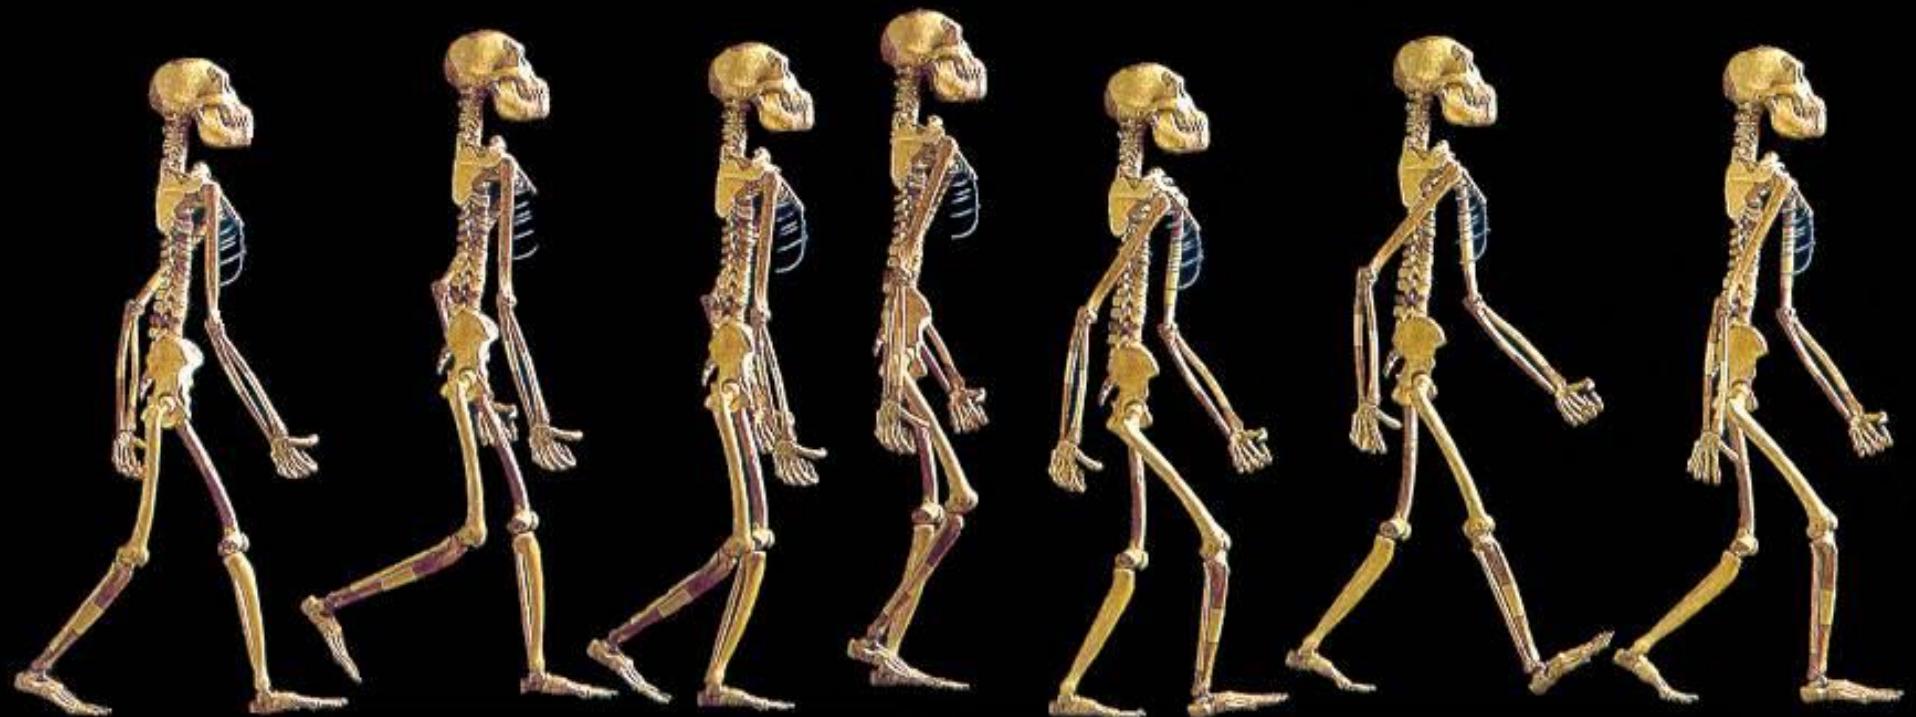

Le falange sono relativamente lunghe e robuste, anche se i metacarpali sono corti come nei umani moderni. Le proporzioni delle mani sono quasi come i umani moderni, con un relativamente lungo pollice e delle dita corte in confronti alle scimmie attuali.

The phalanges are relatively long and robust, although the metacarpals are short, as in humans. Manual proportions are mostly human-like, with a relatively long thumb and short fingers compared with those of extant apes

Le vertebre toraciche indicano che la colonna vertebrale toracica e la gabbia toracica sono diventate human-like almeno 3,4 Ma fa con un invaginazione della colonna vertebrale. Questo può avere accompagnato una riorganizzazione del bacino con una tradizione verso il bipedismo.

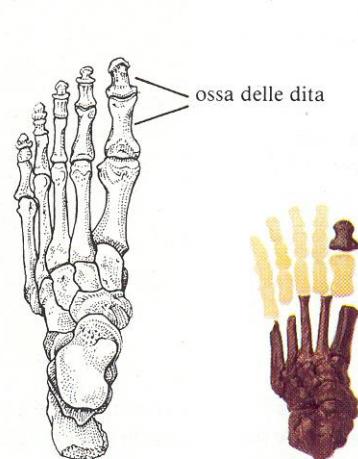

The thoracic vertebrae indicate that the thoracic vertebral column and rib cage had become more human-like by at least 3.4 Ma with invagination of the vertebral column. This change may have accompanied reorganization of the pelvis with the transition to bipedality.

ER 1470 (*H. rudolfensis*)

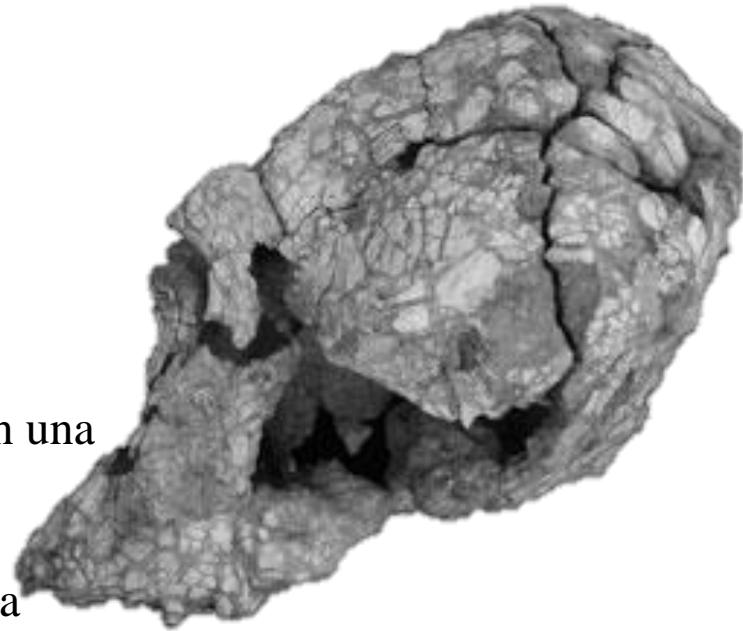

Condivide caratteristiche primitive con *Au. afarensis*

≠ *Au. afarensis* (specie contemporanea)

- Sulla parte inferiore della faccia

Radice del processo maxillo-zigomatico posizionato anteriormente

Piano subnasale trasversalmente e sagittalmente piatto con una proiezione minima oltre i canini

Non ci sono caratteri derivati che potrebbe unirlo alla linea evolutiva *anamensis-afarensis*

Shared primitive features with *Au. afarensis*

≠ *Au. afarensis* (contemporaneous species)

- On the lower part of the face:

anteriorly positioned root of the maxillary zygomatic process transversely and sagittally flat submasal plane with minimal projection beyond the canines

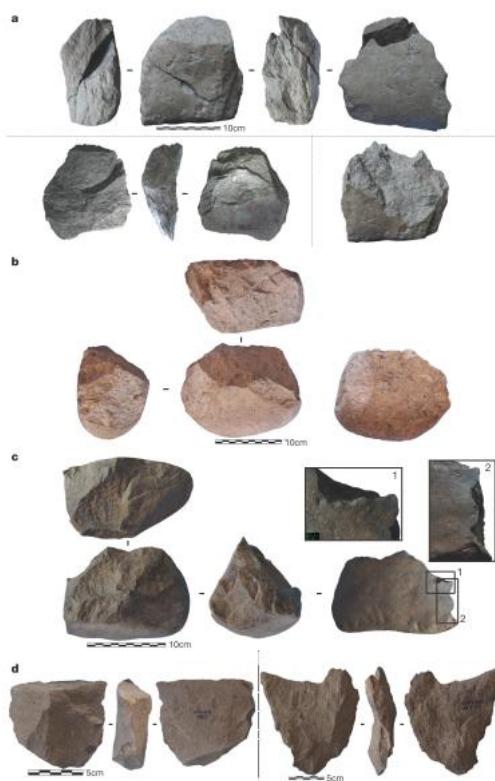

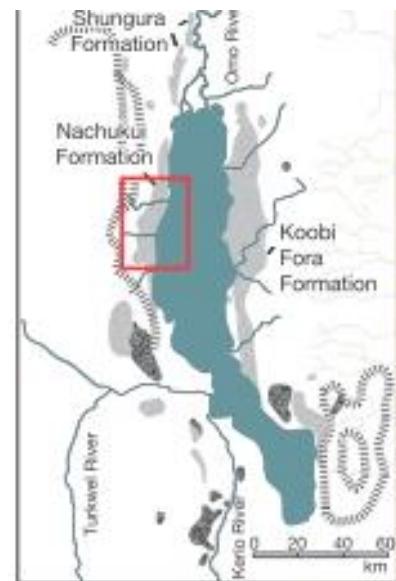

There are no shared derived characters linking it to the *anamensis-afarensis* species-lineage

3.3-million-year-old stone tools from Lomekwi 3, West Turkana, Kenya

Quinn^{3,5,9}, Michel Brunet^{8,10}, Adrian Arroyo², Nicholas Taylor^{2,3}, Sophie Clément^{3,11}, Guillaume Daver¹², Jean-Philip Brugal^{3,13}, Louise Leakey¹, Richard A. Mortlock⁵, James D. Wright⁵, Sammy Lokorodi³, Christopher Kirwa^{3,14}, Dennis V. Kent^{5,6} & Hélène Roche^{2,3}

Human evolutionary scholars have long supposed that the earliest stone tools were made by the genus *Homo* and that this technological development was directly linked to climate change and the spread of savannah grasslands. New fieldwork in West Turkana, Kenya, has identified evidence of much earlier hominin technological behaviour. We report the discovery of Lomekwi 3, a 3.3-million-year-old archaeological site where *in situ* stone artefacts occur in spatio-temporal association with Pliocene hominin fossils in a wooded palaeoenvironment. The Lomekwi 3 knappers, with a developing understanding of stone's fracture properties, combined core reduction with battering activities. Given the implications of the Lomekwi 3 assemblage for models aiming to converge environmental change, hominin evolution and technological origins, we propose for it the name 'Lomekwian', which predates the Oldowan by 700,000 years and marks a new beginning to the known archaeological record.

These finds occur in the same geographic and chronological range as the paratype of *Kenyanthropus platyops* (KNM-WT 38350), other hominin fossils generally referred to cf. *K. platyops*, and one unpublished hominin tooth (KNM-WT 64060) found by WTAP in 2012.

STS 71

- 1,20 m
- 430 – 510 cc
- *More marked cranial curvature than chimp*
- *Supra orbital torus thicker*
- *Foramen magnum in an intermediate position*
- *Large space between the zygomatic arch and the cranium*
- *Marked alveolar prognatism*
- *Parabolic jaw*

1,20 m

- 430 – 510 cc

- Curvatura cranica più marcata che i scimpanzé

- Toro sopra-orbitale più spesso

- Foramen magnum in posizione intermedia

- Grande spazio tra le arcate zigomatiche e il cranio

- Prognatismo alveolare pronunciato

- Mascella parabolica

Au. afarensis

Scattola cranica più alta e corta senza cresta sagittale

Base del cranio stretta relativamente alla sua lunghezza

Foramen magnum situato posteriormente

Pilastro anteriore proeminente che limita l'apertura nasale

Zona subnasale piatta e meno proiettata relativamente all'asse bicanino

Radice del processo zigomatico prende origine anteriormente

Corpo mandibolare più robusto

Denti postcanini più larghi

Au. afarensis

Higher and shorter braincase with rare sagittal cresting

Cranial base narrow relative to its length

Foramen magnum located more posteriorly

Prominent anterior pillars border the nasal aperture

Subnasal plate is flat and much less projecting relative to the bicanine axis

Zygomatic process roots originated more anteriorly

Mandible corpus more robust

Larger postcanine teeth

BOU-BP-12-130

Intermediario tra *Au. afarensis* e i primi appartenenti al genere *Homo*
Combina una faccia e un palato plesiomorfi con una morfologia del calvaria derivata e una configurazione dentaria insolita (denti molto grandi)

Intermediate between Au. afarensis and the first Homo

Combine a largely plesiomorphic face and palate with derived calvaria morphology and a highly unusual hominin dental configuration (huge teeth)

= *Au. afarensis*

Prognatismo pronunciato, zona subnasale convessa, margine dell'apertura nasale affilate, assenza di pilastro, palato poco profondo

Maxillary features: strongly prognathic, convex subnasal surface, sharp lateral margins of the nasal aperture, lack of anterior pillar, shallow palate

Asfaw, B., T.D. White, O. Lovejoy, B. Latimer, S. Simpson, and G. Suwa. 1999. "Australopithecus garhi: A new species of early hominid from Ethiopia." In Science, vol. 284, pp. 629-635

La parte bassa della faccia è prognata con gli incisivi orientate verso il basso.

Le radice dei canini sono posizionati ai lati dei margini dell'apertura nasale.

Il palato è verticalmente sottile

Le radici dei zigomatici si nascondono sopra P4/M1

L'arcata dentaria è a U, con una leggera divergenza dei corpi.

La squama frontale postglabellare è depressa con un trigone frontale.

Presenza di una costrizione post-orbitale

I parietali presentano una cresta sagittale bipartita posizionata anteriormente e che si divide sopra lambda..

La capacità cranica è di circa 450 cc

The lower face is **prognathic** with incisors lying down.

Canine roots are placed quite laterally to the nasal aperture margin.

The palate is vertically thin.

The zygomatic roots originate above P4/M1.

The dental arcade is **U-shaped**, with slightly divergent dental rows.

The postglabellar frontal squama is depressed in a frontal trigon.

There is marked **postorbital constriction**.

The parietal bones have a well-formed, bipartite, anteriorly positioned sagittal crest that divides above lambda.

Cranial capacity of approximately 450 cc (reconstructed)

Femore allungato, diverso da *Pan* e
Au. afarensis, simile a *Homo*
Femur elongated, different from Pan
and Au. Afarensis, similar to Homo

Rapporto braccio/avambraccio vede
l'avambraccio molto sviluppato, come
in *Pan* e *Au. afarensis*

*Relation arm/forearm with the
forearm more developed, like in Pan
and Au. Afarensis.*

Dimorfismo sessuale sembra piuttosto
marcato

Sexual dimorphism rather marked

Possibile persistenza di adattamenti
alla vita arboricola nello scheletro dei
piedi

*Possible persistence of arboreal
locomotion in the foot skeleton*

New species from Ethiopia further expands Middle Pliocene hominin diversity

Yohannes Haile-Selassie^{1,2}, Luis Gibert³, Stephanie M. Melillo⁴, Timothy M. Ryan⁵, Mulugeta Alene⁶, Alan Deino⁷, Naomi E. Levin⁸, Gary Scott⁷ & Beverly Z. Saylor²

Middle Pliocene hominin species diversity has been a subject of debate over the past two decades, particularly after the naming of *Australopithecus bahrelghazali* and *Kenyanthropus platyops* in addition to the well-known species *Australopithecus afarensis*. Further analyses continue to support the proposal that several hominin species co-existed during this time period. Here we recognize a new hominin species (*Australopithecus deyiremeda* sp. nov.) from 3.3–3.5-million-year-old deposits in the Woranso-Mille study area, central Afar, Ethiopia. The new species from Woranso-Mille shows that there were at least two contemporaneous hominin species living in the Afar region of Ethiopia between 3.3 and 3.5 million years ago, and further confirms early hominin taxonomic diversity in eastern Africa during the Middle Pliocene epoch. The morphology of *Au. deyiremeda* also reinforces concerns related to dentognathic (that is, jaws and teeth) homoplasy in Plio-Pleistocene hominins, and shows that some dentognathic features traditionally associated with *Paranthropus* and *Homo* appeared in the fossil record earlier than previously thought.

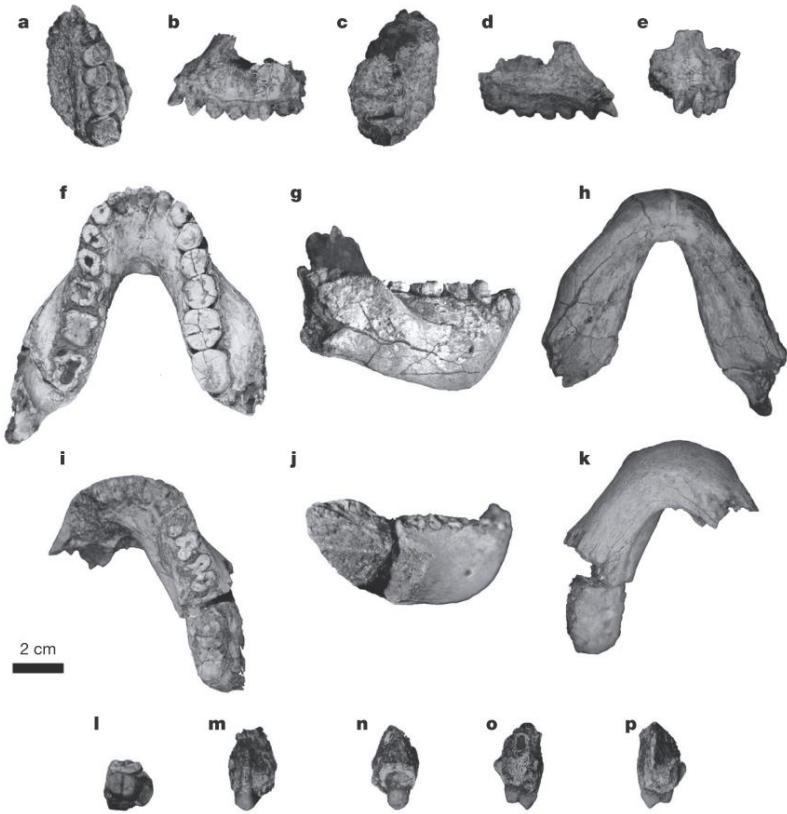

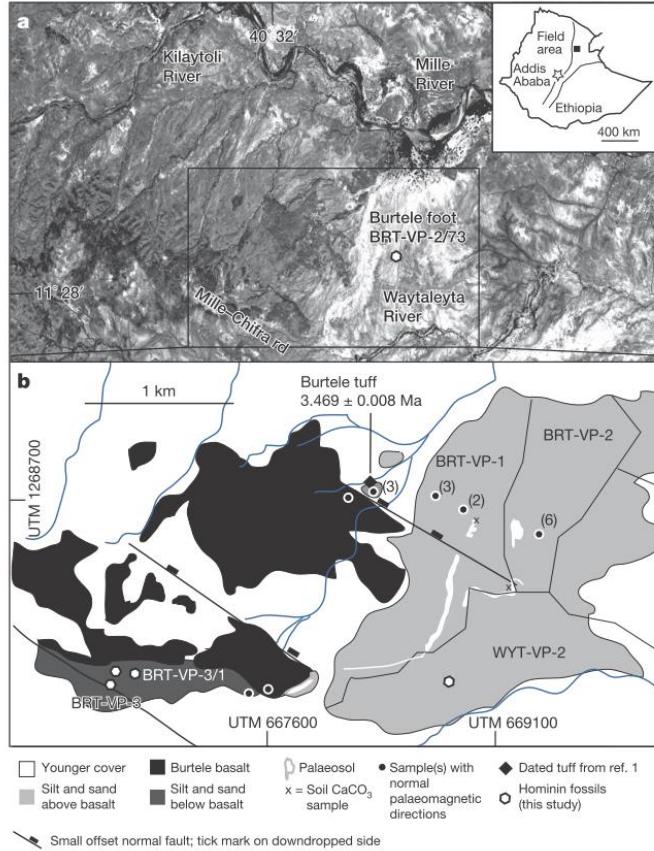

Figure 1 | Holotype BRT-VP-3/1. **a**, Occlusal view. **b**, Lateral view. **c**, Superior view. **d**, Medial view. **e**, Anterior view. Paratype BRT-VP-3/14. **f**, Occlusal view. **g**, Right lateral view. **h**, Basal view. Paratype WYT-VP-2/10. **i**, Occlusal view. **j**, Right lateral view. **k**, Basal view. Referred specimen BRT-VP-3/37. **l**, Occlusal view. **m**, Buccal view. **n**, Lingual view. **o**, Distal view. **p**, Mesial view.

Diagnosi differenziale: *Au. deyiremeda* è

≠ *Ar. ramidus* per: smalto molto più spesso, P4 con 3 radice e una mandibola robusta

≠ *Au. anamensis* per un profilo della sifnisi mandibolare poco sfuggente, un corpo mandibolare più robusto, una P3 bicuspide

≠ *Au. afarensis* per l'architettura generale della mandibola, mancanza di un corpo laterale incavato, dente superiore postcanine più piccole.

≠ *Au garhi* per il suo prognatismo subnasale ridotto e le dimensione ridotte dei canini e post-canini.

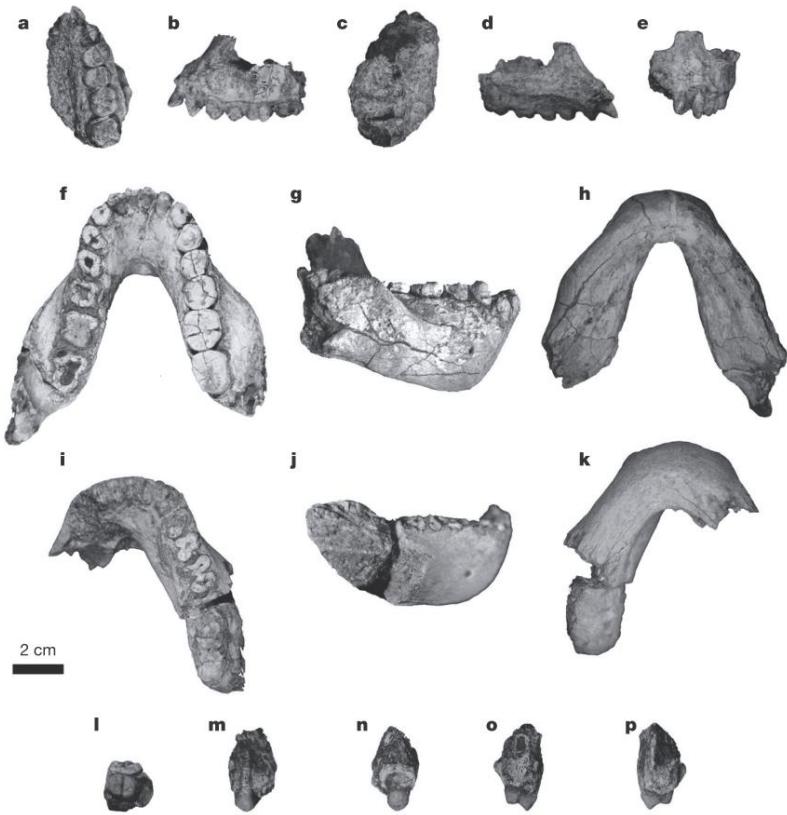

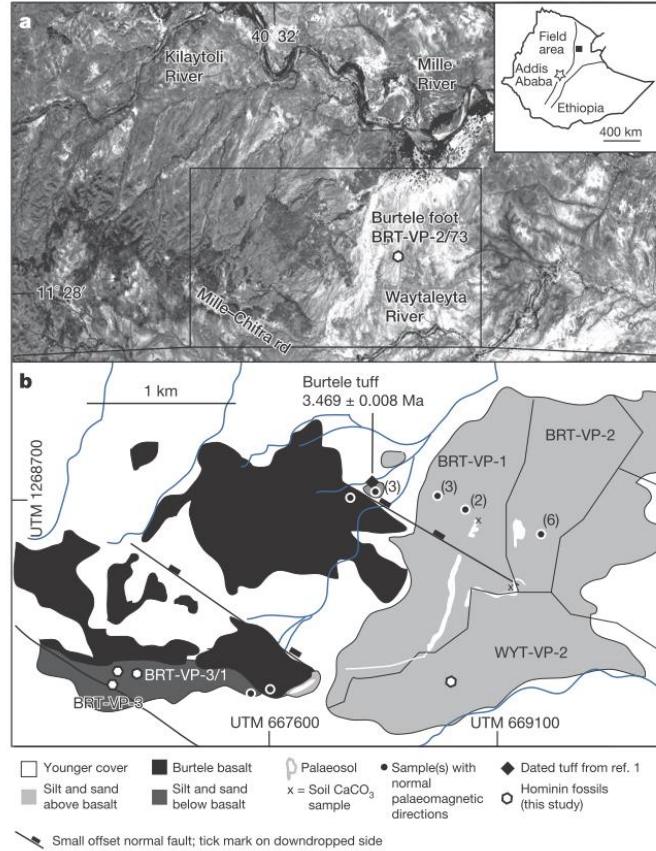

Figure 1 | Holotype BRT-VP-3/1. **a**, Occlusal view. **b**, Lateral view. **c**, Superior view. **d**, Medial view. **e**, Anterior view. Paratype BRT-VP-3/14. **f**, Occlusal view. **g**, Right lateral view. **h**, Basal view. Paratype WYT-VP-2/10. **i**, Occlusal view. **j**, Right lateral view. **k**, Basal view. Referred specimen BRT-VP-3/37. **l**, Occlusal view. **m**, Buccal view. **n**, Lingual view. **o**, Distal view. **p**, Mesial view.

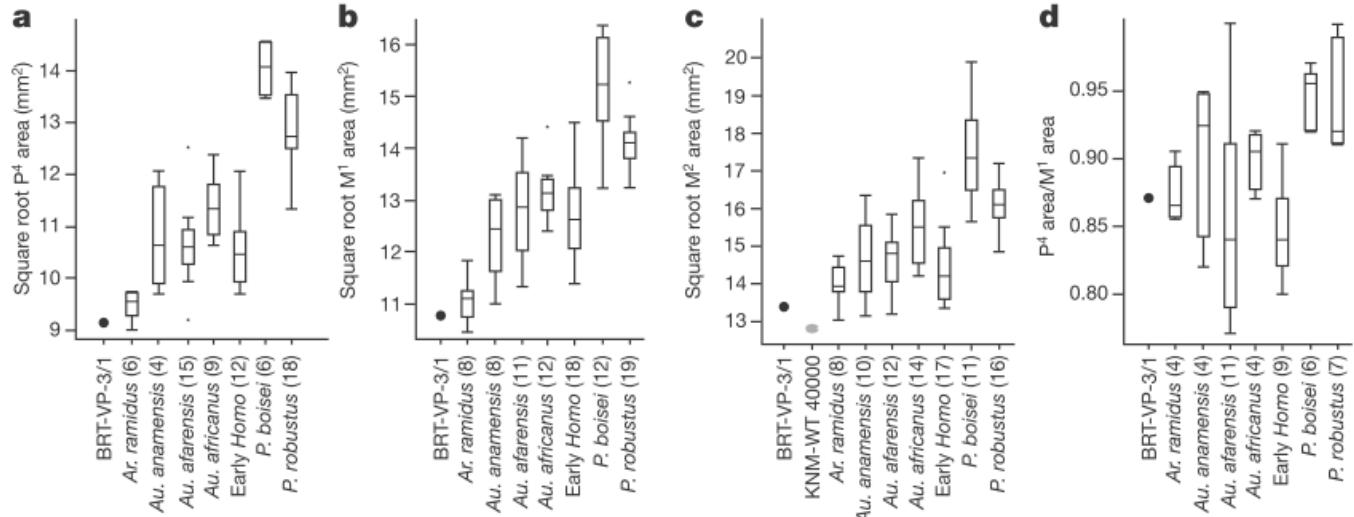

Differential diagnosis : *Au. deyiremeda* is

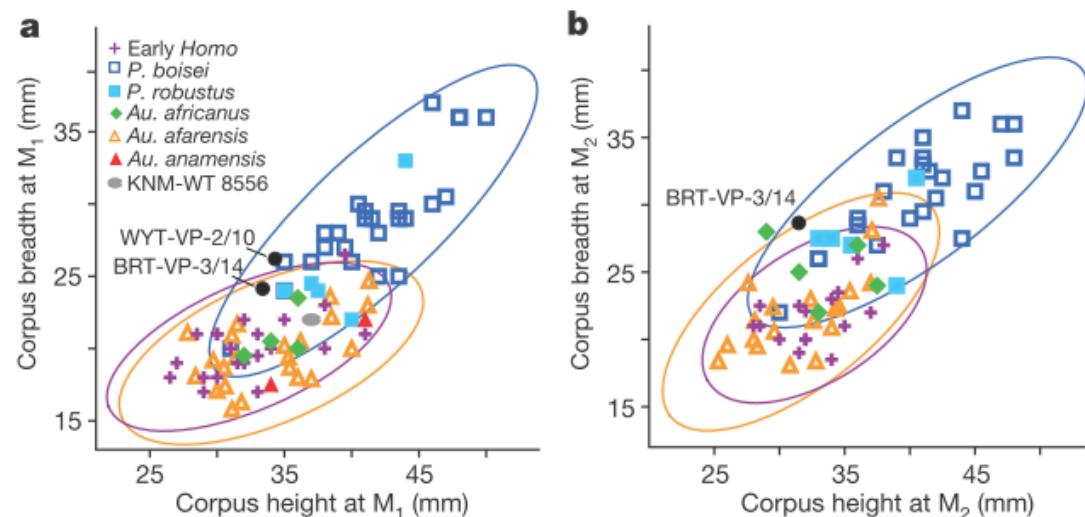

≠ *Ar. ramidus* in having absolutely thicker enamel on its molars, a P 4 with three-roots, a robust mandible. ≠ *Au. anamensis* in lacking an extremely receding mandibular symphysis, having a more robust mandibular corpus and a bicuspid P 3.

≠ *Au. afarensis* by its overall mandibular architecture, including the lack of a lateral corpus hollow, the reduced dimension of the postcanine maxillary

≠ *Au garhi* by its reduced subnasal prognathism and absolutely smaller canines and postcanine dentition.

Confronto delle dimensione dentarie / *dental dimensions comparison*

Confronto delle dimensione mandibolare / *mandibular dimensions comparison*

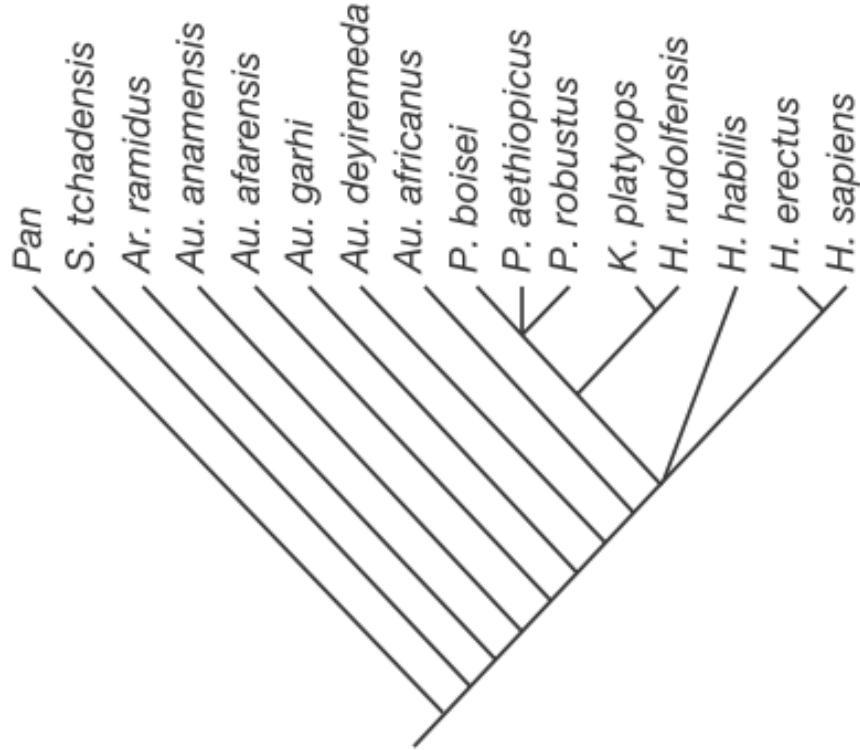

Figure 6 | Cladogram depicting the majority-rule consensus of 17 equally parsimonious trees that result from a phylogenetic analysis of the features preserved in the *Au. deyiremeda* hypodigm. Tree length = 63, consistency index = 0.63. The position of *Au. garhi* and topologies within the *Paranthropus* + *Kenyanthropus* + *Homo* clade are unstable when these features are considered. However, *Au. deyiremeda* is consistently placed as a sister taxon to a clade that includes *Au. africanus*, *Paranthropus*, and *Homo* (see Supplementary Notes 6–8 for further details).

Australopithecus sediba: A New Species of *Homo*-Like Australopith from South Africa

Lee R. Berger,^{1,2*} Darryl J. de Ruiter,^{3,1} Steven E. Churchill,^{4,1} Peter Schmid,^{5,1} Kristian J. Carlson,^{1,6} Paul H. G. M. Dirks,^{2,7} Job M. Kibii¹

Despite a rich African Plio-Pleistocene hominin fossil record, the ancestry of *Homo* and its relation to earlier australopithecines remain unresolved. Here we report on two partial skeletons with an age of 1.95 to 1.78 million years. The fossils were encased in cave deposits at the Malapa site in South Africa. The skeletons were found close together and are directly associated with craniodental remains. Together they represent a new species of *Australopithecus* that is probably descended from *Australopithecus africanus*. Combined craniodental and postcranial evidence demonstrates that this new species shares more derived features with early *Homo* than any other australopith species and thus might help reveal the ancestor of that genus.

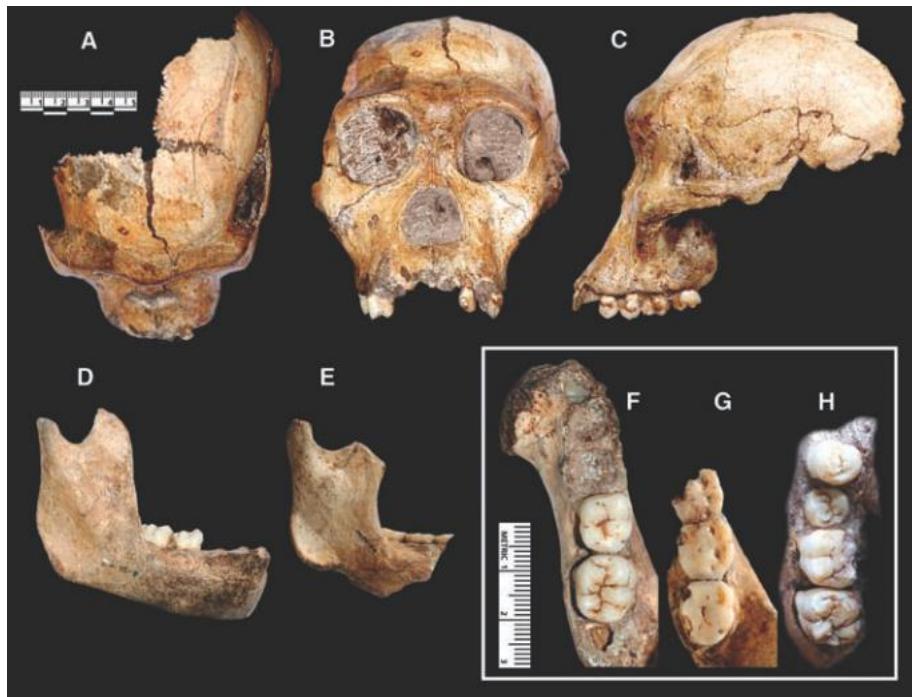

Età: 1,95 e 1,78 Ma

Sito: Malapa, Sudafrica

Resti: 2 scheletri parziali

Caratteristiche:
condividono più caratteri derivati con i primi *Homo* che tutti i altri Australopitecine

Craniodontali elementi di *Au. sediba*. UW88-50 (MH1) cranio juvenile in (A) superiore, (B) frontale, e (C) vista laterale sinistra.
(D) UW88-8 (MH1) mandibola juvenile in vista laterale destra, (E) UW88-54 (MH2) mandibola adulta in vista laterale destra, (F) UW88-8 mandibola in vista occlusiva,
(G) UW 88-54 mandibola in vista occlusiva, e
(H) UW 88-50 maxilla destra in vista occlusiva (i barri di scala sono in centimetri).

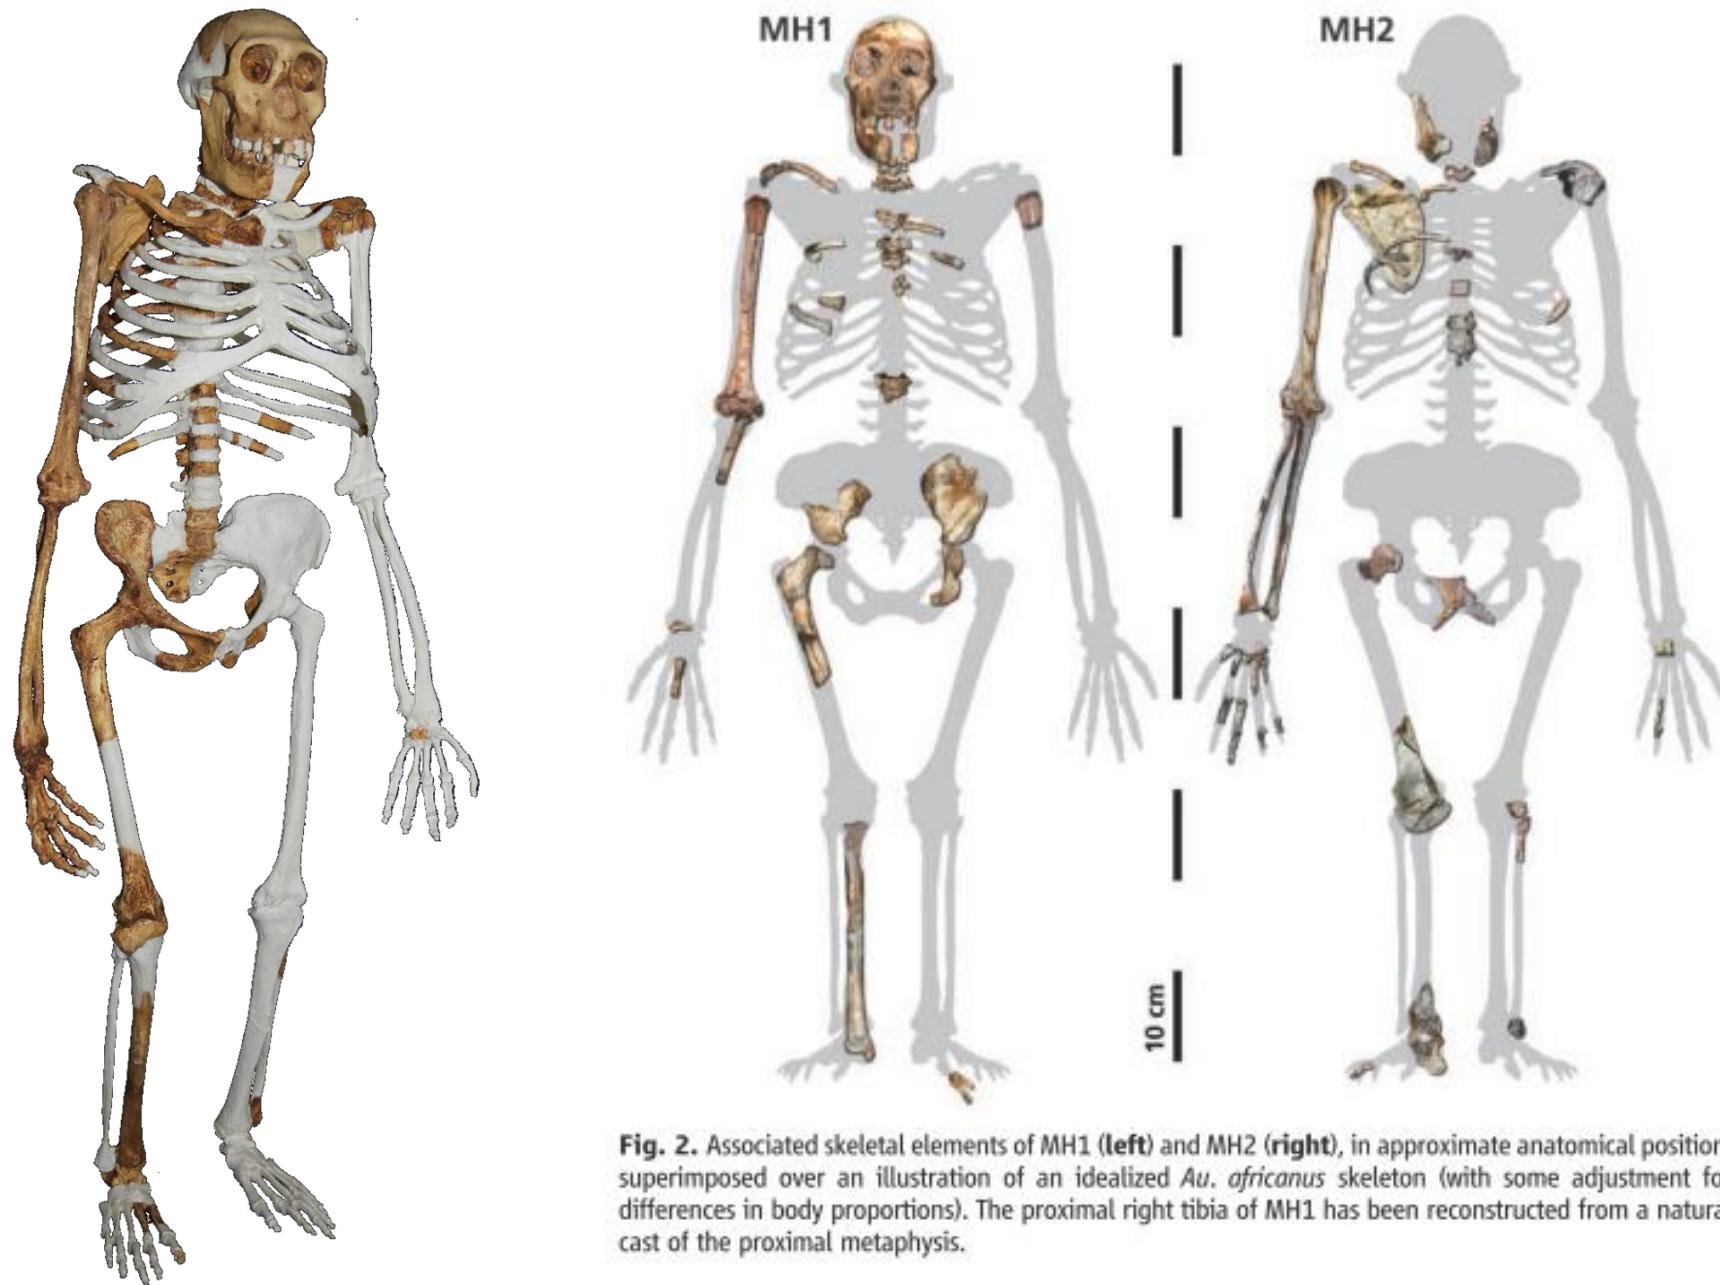

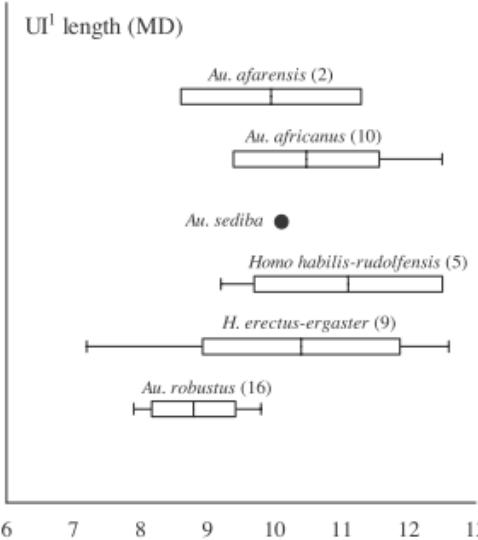

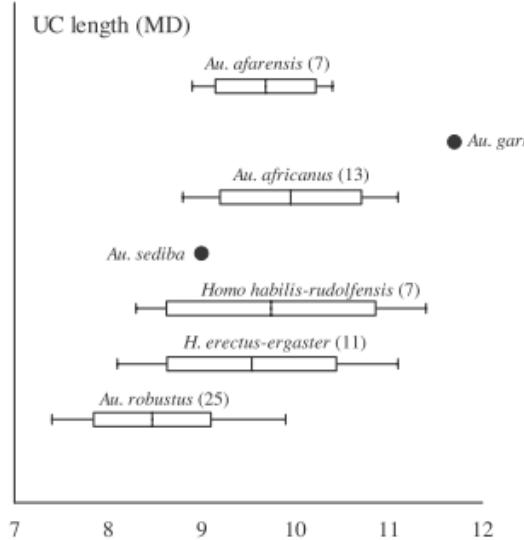

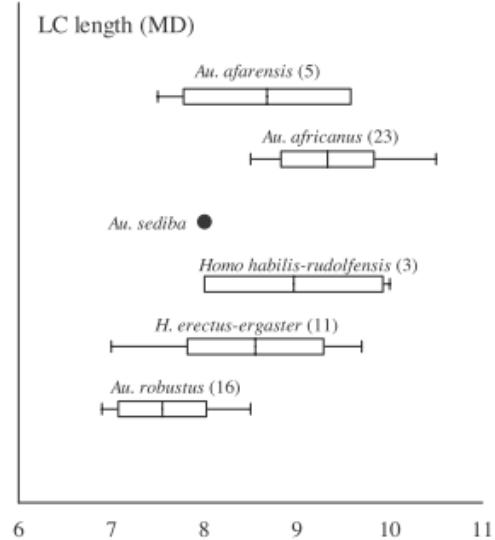

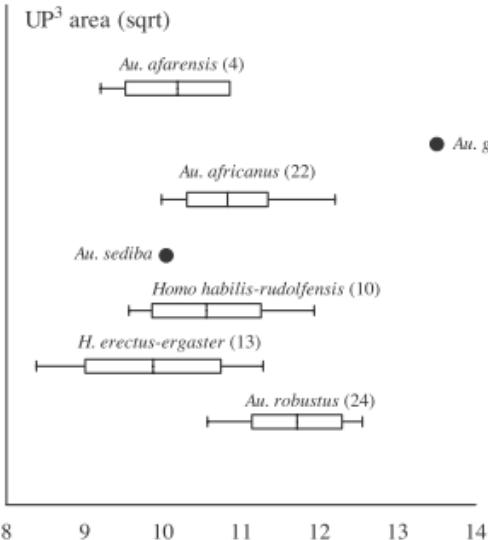

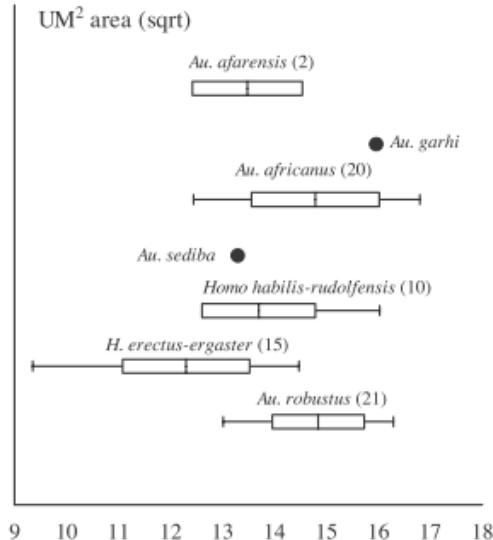

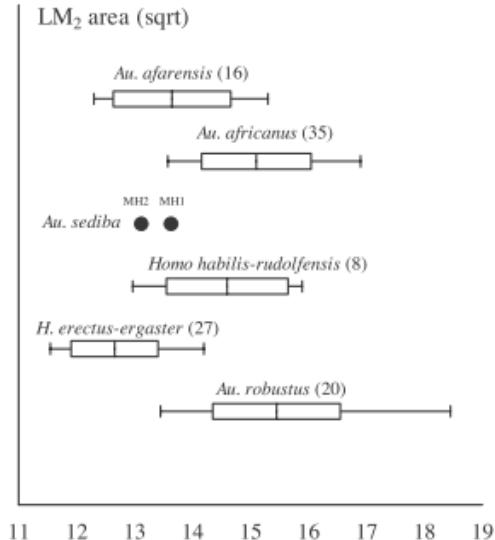

Fig. 2. Associated skeletal elements of MH1 (left) and MH2 (right), in approximate anatomical position, superimposed over an illustration of an idealized *Au. africanus* skeleton (with some adjustment for differences in body proportions). The proximal right tibia of MH1 has been reconstructed from a natural cast of the proximal metaphysis.

A**B****C****D****E****F**

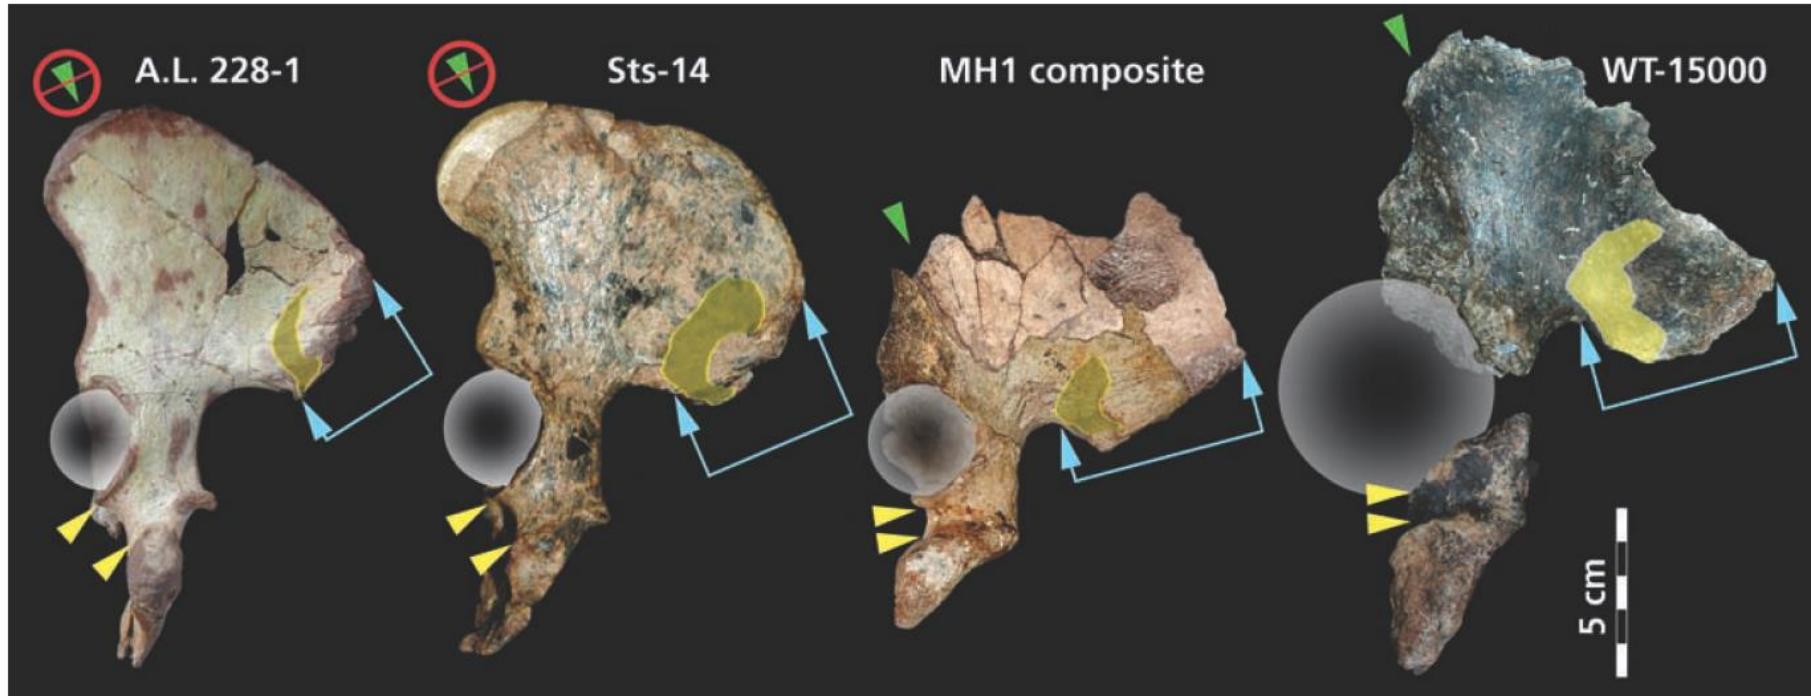

Fig. 4. Representative ossa coxae, in lateral view, from left to right, of *Au. afarensis* (AL 228-1), *Au. africanus* (Sts 14), *Au. sediba* (MH1), and *H. erectus* (KNM-WT 15000). The specimens are oriented so that the iliac blades all lie in the plane of the photograph (which thus leads to differences between specimens in the orientation of the acetabula and ischial tuberosities). MH1 possesses derived, *Homo*-like morphology compared to other australopithecines, including a relative reduction in the weight transfer distance from the sacroiliac (yellow) to hip (circle)

joints; expansion of the retroauricular surface of the ilium (blue arrows) (determined by striking a line from the center of the sphere representing the femoral head to the most distant point on the posterior ilium; the superior arrow marks the terminus of this line, and the inferior arrow marks the intersection of this line with the most anterior point on the auricular face); narrowing of the tuberoacetabular sulcus (delimited by yellow arrows); and pronouncement of the acetabulocristal (green arrows) and acetabulosacral buttresses.

In confronto ai altri Australopitecini, MH1 possiede una morfologia *Homo*-like, coinvolgendo anche una riduzione relativa del trasferimento di peso dal sacroiliaco (giallo) alla giunzione dell'anca (cerchio)
